cause of decay and to devise means for its elimination. No caries reduction program encountered thus far has succeeded in delivering any considerable segment of a mass population into adult life with an average caries experience rate of about 3 and a complete absence of decay in approximately one-third of a native population, as has the use of a domestic water supply in which fluorine is a natural constituent. Some twenty-five communities in this country have accepted the evidence as sufficiently conclusive to warrant the addition of fluoride in a proper proportion to their domestic water supplies as a means of reducing the decay rate. If in the future some method of further reducing the decay rate should be available, it need not necessarily be in conflict with the action exerted by fluorine.

Sixth Annual Meeting United States-Mexico Border Public Health Association

The Sixth Annual Meeting of the United States-Mexico Border Public Health Association was held in Laredo, Tex., and Nuevo Laredo, Mexico, March 20-22. Nearly 300 persons were in attendance with almost as many from the South of the Border as from the North.

Sessions were held on international coöperation in health, on Border sanitation, on tuberculosis and its control, with special reference to BCG, on meningitis and other communicable diseases, and on the problems confronting the mother and child. Excellent exhibits were shown from the Section on Public Health Education of the Ministry of Health and Welfare of Mexico. Coöperating agencies beside the Ministry of Health were the U. S. Public Health Service, the Ministry of Hydraulics in Mexico, the Ministry of Agriculture in Mexico, the Institute of

Inter-American Affairs, the U. S. Children's Bureau, the International Boundary and Water Commission, the Rockefeller Foundation, the University of Vera Cruz, the Texas Tuberculosis Association, the Crippled Children's Foundation, and the Pan American Sanitary Bureau.

It was decided to hold the meeting in 1949 at Nogales, Ariz., and Nogales Sonora, Mexico.

The new officers for the Border Public Health Association were elected as follows.

President: Dr. Victor Ocampo Alonzo, Hermosillo, Sonora

President-Elect: Dr. George W. Cox, Austin, Tex.

Vice-Presidents: Dr. Jose Angulo Araico, Mexicali, Baja, Calif.; Dr. J. P. Ward, Phoenix, Ariz.

Secretary: Dr. M. F. Haralson, El Paso, Tex.
Pro-Secretary: Dr. Gustavo A. Rovirosa, El Paso, Tex.

Role of the State Health Department in the School Dental Program*

J. M. WISAN, D.D.S., M.S.P.H., F.A.P.H.A.

Dental Director, State Department of Health, Trenton, N. J.†

STATE departments of health are accepting six responsibilities¹ in the conduct of school dental programs. Briefly, these responsibilities are:

1. Studying and planning for the solution of dental health problems
2. Coördinating and advising local agencies
3. Subsidizing local programs
4. Establishing standards for dental programs
5. Disseminating authentic dental health information
6. Coöperating with other state agencies

While the listed functions indicate that state departments of health are exhibiting characteristics of leadership, the actual performance in conducting school dental programs does and should rest with local personnel.² The state department of health within this concept functions as an interagency. How indispensable local participation is for meeting dental health needs will be discussed under each of the listed functions.

1. *Studying and planning for the solution of dental health problems*—A local board of education or a local board of health conducts surveys to determine the prevalence of dental defects among school children. It is desirable that local personnel be aware of the dental needs of their children. However, the value of the findings will be enhanced if local

authorities are able to compare conditions found in their community with conditions found in other situations.³ By utilizing comparable data obtained under similar or nearly similar conditions, the effectiveness of program technics can be evaluated. Not only can results of programs be reliably measured, but also costs can be accurately estimated by uniform reports.⁴

State departments of health should designate inspection charts and recommend techniques for dental surveys, so that uniform procedures may be utilized throughout the state. After dental conditions found in local areas are carefully analyzed, the state department will be able to make recommendations for dental programs, not by theoretical armchair thinking but by accurate estimates.

A number of state departments of health are conducting demonstration and research projects. Among the phases being studied are the fluorination of communal water supplies, the topical application of 2 per cent sodium fluoride, incremental dental care procedures for children, dental care time estimates, and evaluation of health education devices.

2. *Coördinating and advising local agencies*—When local dental programs are supported by health, welfare, and educational agencies, maximum results may be expected; but competent leadership is required to develop such coördination. When requested to do so, a state dental administrator usually finds it less difficult to accomplish rapport of local personnel than does a home-town

* Presented before a Joint Session of the American School Health Association and the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

† Present address: Director, Division of Dental Health Education, American Dental Association, Chicago, Ill.

official. Moreover, because of his objective viewpoint, a state administrator is better able to recommend desirable changes or improvements.

In New Jersey the dental health division of the State Department of Health has found it profitable to help organize dental health committees representing local schools, health departments, nurses, dental hygienists, parents and teachers, and other groups interested in child health. In some instances, these dental committees operate solely to promote the dental program; in other places, they operate as subcommittees of health councils or committees.⁶

3. *Subsidizing local programs*—Many rural and suburban communities have neither facilities nor funds to maintain effective dental programs. Particularly is this true of dental treatment programs. State departments, being the agents for distributing federal and state health funds, are able to subsidize dental care programs in the sparsely populated areas.

However, contributing money does not warrant the establishment of authoritarian policies by a state department. Such details as designating children entitled to treatment, scheduling treatment hours, appointing dentists, might well be the responsibilities of local agencies. Also, local personnel might profitably be permitted to decide whether clinics, private offices, or mobile clinics are to be utilized. Moreover, the local dental society should be invited to recommend policies for the program.

Subsidies provided by state departments of health may take several forms. The state may pay all or part of the salaries of dentists; dental equipment and supplies may be provided. In rural areas, many state departments are providing trailers, automobile clinics, station wagons, or portable dental equipment.

Some communities will find it necessary to have the state dental adminis-

trator help in supervising dentists participating in the local dental program. When requested, and only when requested, such supervision should be provided because competent professional supervision of a dental care program will improve standards of treatment.

4. *Establishing standards for dental programs*—Under the heading "Subsidizing Local Programs," the need of assigning responsibilities to local agencies was stressed. However, local school administrators should seek the advice of state dental directors before instituting dental programs. Most state dental directors are following the recommendations of the U. S. Public Health Service, the Children's Bureau, the Council on Dental Health of the American Dental Association, the American Association of Public Health Dentists, and the National Committee on School Health Policies. The following are a few of the basic policies recommended:

a. Simplified and uniform examination procedures should be used.⁴

b. Record forms approved by the American Association of Public Health Dentists should be utilized.⁷

c. Dental treatment programs should begin with younger children with subsequent incremental care provided.⁸

d. Topical applications of 2 per cent sodium fluoride should be provided four times a year for children.⁹

e. All necessary fillings and extractions should be provided for children included in the community treatment programs.¹⁰

f. Authentic dental health information should be used as content material in the health education programs.

g. Desirable motivating devices should be used in the health education programs.

If the state department of health is to fulfil this role of establishing standards for dental programs, recommendations should be presented in printed or mimeographed leaflets.¹¹ To obtain uniform data, the state department should print forms and charts in large numbers so that they can be either distributed free to local agencies or sold at cost.

5. *Disseminating authentic dental health information*—Physical education personnel and classroom teachers require guidance in selecting dental health education material. The dental bureau of the state department of health should be prepared to offer this guidance by means of field visits or by printed or mimeographed material. Informative leaflets, source units, and manuals, have been printed by state departments of health. Also, nearly all state departments purchase material published by the American Dental Association for distribution among local personnel.

State departments of health should organize state and local committees to prepare dental health education material.^{12, 13} This collaboration is highly recommended because it results in broader concepts and avoids the disadvantages of specialized thinking. State departments of education, state departments of health, state dental societies, state departments of welfare, state agricultural colleges, state teachers colleges, dental schools, state nursing organizations, state organizations for physical education, may collaborate in preparing authentic dental health education material.

The distribution of visual aids, such as movies, slides, posters, models, and charts, has been found worth while, particularly if directions for their proper use accompany the material. Health educators have informed us that visual aids as well as printed materials are to be used only as tools; that the chief objective of health education is not mere information but desirable changes of dental health practices.

6. *Coöperating with other state agencies*—Equally as important as coördination of local agencies in the conduct of local dental programs is the collaboration of all state health, welfare, and educational agencies for dental objectives. In most states we find a number of state agencies, both official and non-

official, involved in local school health programs. Since their policies are usually set by their state administrators or state officers, it is imperative that the state dental bureau work closely with these state organizations. In the case of welfare agencies and such nonofficial groups as a state congress of parents and teachers, procedures in the local areas are directed by the state leaders. After the state dental director has cleared with the state office, it is much easier to function with the local representatives of these state groups.

SUMMARY

It has been shown that the state department of health may operate as an interagency encouraging effective dental health programs in local communities. If it accepts this responsibility by employing democratic techniques, maximum results will be obtained by providing expert guidance on the state level and encouraging active participation in the local communities.

Health Problems Resulting from Newer Technological Developments*

R. EMMET KELLY, M.D.

Medical Director, Monsanto Chemical Company, St. Louis, Mo.

THE health problems associated with the newer technology have been most prominent ever since the news of the atom bomb was released. Other wartime and post-war developments have contributed to our peacetime health hazards. Before discussing some of these, I wish to emphasize two related facts.

The first is that not all of the old problems of industrial medicine have been solved. On the contrary, new ones have arisen in the use of materials that well qualified observers had previously assumed were well controlled. For example, an innocuous substance such as talc, or at any rate one formerly believed to be innocuous, is now being investigated as a cause of pulmonary disability. Likewise, workers who have been employed in atmospheres well under the maximum allowable concentration of silica appear in some cases to be developing silicosis. Thus, as there is an advancing front of medical problems arising from the contact with newer products, a struggle in the rear areas with the old compounds continues.

The second point is that much of the newer information is still not generally available because of security restrictions. This includes important medical and industrial observations on microwaves, biological warfare, and radioactive materials.

The advance in industry has developed along several pathways. I will discuss only the five most prominent: radioactive materials, newer chemicals—both in substance and application—newer metals, microwaves, and ultrasonic waves.

Radioactive materials have been rightly considered by the lay and the professional public to be the key to the technology of the future. We are limiting ourselves in this discussion to health problems, and so the many actual and potential benefits which radioactive isotopes afford to medicine and industry will not be dwelt upon.

To evaluate the health hazards associated with this field, let us see what the exposure is, how widespread it will be, and what ill effects have been reported to date.

Radioactive materials emit a variety of radiations but they all exert effects that are roughly similar. The deleterious effect on human beings is produced by setting up destructive ionizing reactions in the tissue. The response varies with the type and amount of exposure. Damage to the germinal cells, the bone marrow, and the lymphatic tissue, and the occurrence of malignant changes comprise the conditions to be expected and guarded against. Experimentally, these results are easily demonstrated. Exposure to sufficient gamma radiation or the introduction of an alpha emitter in a sufficient quantity (and remember even a fantastically small amount may be a sufficient quantity) has produced sterility.

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

Leukemia has resulted from bombardment from a neutron source, and a variety of malignancies have been produced by exposure to fission products. The work of Brues, Lisco, and Finkel,¹ as reported at the 1946 Gibson Island Research Conference on Cancer, is interesting in this connection. Using strontium (Sr^{90}), bone tumors and lymphoma were produced; yttrium 91 (Y^{91}) caused intestinal lesions with obstruction, and plutonium (Pu^{239}) caused splenic atrophy and gross liver damage. After the subcutaneous injection of one gamma of Pu^{239} localized fibrosarcomas appeared within one year, and localized ulcerative lesions and spontaneous amputations occurred.

Obviously, radioactive substances are inherently hazardous, but can they be handled and used safely? The answer is uncompromisingly yes. Before developing this statement, let us consider how widespread is their use.

On August 2, 1946, the first shipment of radioactive isotopes produced in the chain reacting pile at the Clinton Laboratories at Oak Ridge, Tenn., was made to the Barnard Free Skin and Cancer Hospital in St. Louis. During the following year over 1,000 shipments were made throughout the continental United States and the Territory of Hawaii. These shipments approximated 1,500,000 miles, and were sent to about 150 scientific and research institutions. These isotopes are being used in fundamental research, in medical research and treatment, in cancer study and treatment, in biological research, and in industrial research. Radioactive isotopes are used in oil well logging, in metallurgy, in aircraft engine development, and in structural analysis of heavy objects, such as castings and girders. In agriculture, tracer elements are used to study soil chemistry, plant hormones, photosynthesis, and the entomological aspect of farming.

To date no ill effects, apart from

accidental exposure, have been observed as a result of the industrial use of radioactive isotopes. The reason for this is simple. It gives no grounds for complacency but rather an indication of what control measures must be exercised in the future. Effects from chronic radiation have not occurred because careful attention to details of protection has made the production, transportation, and use of these isotopes safe. For example, at Clinton Laboratories the budget of the health physics group amounts to more than \$250,000 annually. Their job is monitoring and supervising the radioactive material from the time it enters the pile until final disposal occurs. Shipping containers vary from less than a pound to a ton, averaging 150 lbs. In one case a 23 gm. unit (approximately the weight of a half dollar) containing radioactive cobalt (Co^{60}) was shipped in a container weighing 1,600 lbs. Other meticulous details are carried out, such as checking the radiation of truck wheels before trucks leave the laboratory to avoid radiation damage to the driver in the event of changing a tire.

It has been shown that radioactive materials can be manufactured, transported, and used safely. Maximum allowable concentrations have been established for all types of radiation. The methods of detection and the means of protection from radiation are so adequate and well tested that only the careless, the uninformed, or the foolhardy should suffer exposure. This is borne out by the record of the Manhattan District plants and the Atomic Energy Commission installations, as well as by the absence of injury to the 70,000 people taking part in the Bikini experiments.

For the future I see three health problems in this field. The first is accidents and their prevention. When working with fissionable products there can be spills, breaks, and other unfore-

Health

...es that will produce
...cient to cause serious in-
ch. This has occurred and,
, will continue, but the inci-
...as been and should be very
The second is unfamiliarity or in-
...cient knowledge of how to handle
...se materials. As the number of in-
...stitutions using these products swells
from 150 to the thousands, there will
be workers who will not abide by the
tolerances and safety rules laid down.
Then too, more detail work will be per-
formed by individuals lacking the
physicist's viewpoint.

The following example is typical of what might be expected: In a southern hospital a medical technician was carrying out analytical procedures with a radioactive substance (which parenthetically was not received from the Atomic Energy Commission) in a manner which was subjecting her to total radiation of many times tolerance. Her superior had failed to assure himself that everyone in the laboratory knew and practised the essentials of protection. As the actual work stems down farther and farther from the individual to whom the material is sent, this hazard grows. One need only couple the deformities and skin cancers of our early radiologists with the fact that present radiologists have a leukemia rate eight times that of males of a comparable age, to understand that progress in protection for scientific workers comes slowly. We then receive a view of what may be in store for workers in the future unless adequate supervision is maintained.

The third problem is that of chronic low level exposure. Most investigators and workers will be using negligible amounts of radioactivity in tracer experiments, and only simple precautions will be needed. However, when we calculate the sum total of all the radioactive isotopes used over the entire country, and as some (carbon 14 for

example) have a half life of over 5,000 years, the serious character of the disposal problem becomes evident. Simply diluting the material and letting it pass into our streams and rivers will not suffice. The radiation would continue and be built up with successive disposals. This problem is being investigated by everyone concerned, but the final answer has not been found.

The industrial chemical field is broadening too rapidly and too extensively for me to do more than select one company as an example of the methods of handling the problems associated with new products. In 1946 this company developed over 50 new products, and it is expected that in 1947 at least as many more will be produced.

The problem for a manufacturing concern is to make certain that no product is used in a manner in which systemic toxicity or skin irritation might result to its workers or consumers. It is impossible to obtain toxicological information on 50 or so compounds in a year, but those compounds that have an application where ingestion or skin contact is a factor must be examined.

For example, every new textile chemical, such as the melamine resins, is subjected to a laboratory study for systemic and skin reaction, culminating in patch testing on 200 human subjects. With plastics and plasticizers, animal experimentation, involving in some cases two year feeding tests, must be made before they can be marketed. Some substances, such as polystyrene and some plasticizers, are so innocuous that they can be used in any application, while the use of others must be more limited.

Certain new chemicals used as biocides, such as hexaethyl tetraphosphate or sodium fluoracetate, possess a high level of toxicity, and investigations must be carried out on their pharmacological activity to allow them to be used safely.

Simply stated, the problem for the

megacycles per second or higher. Their wave length varies from 30 cm. to 1 cm. These radiations had been generated prior to 1939 but their wartime use in radar vastly stimulated their use and development. These high frequency radiations are the basis of the electronic field and have wide industrial application. It is important that their effect on the workers be determined.

Microwaves have optical properties. They can be focused and may be selectively absorbed by various media such as water, oxygen, and, presumably, tissue. Up to now the only biological effect noted has been the production of heat similar to medical diathermy. There has been no ill effect discovered either clinically in workers or experimentally in animals.³⁻⁵ Studies have been carried out on animals exposed to continuous radiations 3 hours a day for 53 days. There were no gross or microscopic tissue changes, and no effects noted on growth or reproduction.

One group of 45 men who were exposed while operating radar for 2 months to 9 years, and another group of 124 men who were exposed for 2 months to 3 years, were examined. There were no abnormal clinical or laboratory findings and no effect on the blood forming or reproductive systems was found. It appears therefore to be fairly well established that the present high frequency radiations exert no ill effect on exposed workers. Future scientific developments in this field, however, must be accompanied by biological experimentation because we cannot assume that wave lengths of new frequencies will not cause damage.

Ultrasonic waves, sometimes called supersonic waves, are elastic vibrations in any solid, liquid, or gaseous medium of a frequency above the range of audible sound (16,000 cycles per second). Their application has varied from submarine detection to the soundless dog whistle, but while at present

it is limited, much future development may occur. Ultrasonic apparatus has been devised which transmits silent sound vibrations powerful enough to ignite paper, and has been considered for such applications as eliminating bacteria and molds, drying inks, and breaking up suspensions of solid particles.

Ultrasonic waves follow the physical laws of audible sound with the addition of some phenomena due to their high frequency. Biologically, they exert a very different effect. Since 1928 ultrasound has been shown to have destructive capabilities for biological tissue. The changes induced vary from simple heat generation to cell rupture. Sudden explosive liberation of dissolved gases in the target tissue has occurred. In one experiment, 37 animals were subjected for 5 to 15 minutes to focused ultrasound produced by expansion and contraction of a quartz crystal.⁶ Reversible and irreversible nerve tissue damage was produced, causing cortical blindness, paralysis, ataxia, or death.

In this experiment the sound traveled only a few millimeters to the animal but it is possible that future industrial exposure to ultrasonic waves may be dangerous. The indications are that the danger limits will turn out to be very high and probably will be encountered only under special conditions. There have been no studies on this phase of the problem in the literature as yet but obviously they are indicated.

The problems already discussed constitute an important but incomplete segment of our newer peacetime technology. I have not included the problems of the new developments in aviation, in industrial biology, in acceleration, or temperature changes. There has been no mention made of the new weapons of destruction—the radioactive cloud, the atom bomb and biological warfare, or the results associated with them. An attempt has been made to omit the purely theoretical advances

Proposed Report on the Educational Qualifications of Community Health Educators^{*†}

I. GENERAL SCOPE OF HEALTH EDUCATION

The health educator helps individuals and groups to recognize, understand, and share responsibility in solving personal, family, occupational, and community health problems. From facts secured with the aid of technical specialists, he interprets health needs, desirable health behavior, and the services of professional health agencies. He develops situations in which actual learning takes place on the basis of factual data provided by technical experts in medicine, dentistry, engineering, nursing, nutrition, and other sciences.

A successful total program of health education in a community requires more than publicity alone. It requires the development of satisfactory learning experiences within organized groups in school and community. It includes the training of other personnel, in the fields of health and of education, to make effective use of the educational opportunities presented by their contacts with individuals and groups. The health educator supplements, in an organized and continuous way, the work of other

educators and public health workers, but he replaces none of them.

The first program of study in health education ever offered in a school of public health was established in 1921. Since that time the emphasis upon health education and the demand for properly trained health educators has constantly increased. Health education is now an important field of service in the modern public health program, with recognized techniques and procedures.

The Committee on Planning in Health Education of the Public Health Education Section of this Association, in an unpublished report, estimates that about 460 health educators are now employed by health agencies, about 300 of whom have completed graduate courses in recognized schools of public health. A survey by the committee at the beginning of 1947 indicated that these health educators were distributed as follows:

| | |
|------------------------------------|-----|
| Federal health organizations | 14 |
| State health departments | 160 |
| City and county health departments | 126 |
| Voluntary health agencies | 160 |
| Total | 460 |

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council, in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

† This proposed report is a revision of the Report on the Educational Qualifications of Health Educators approved by the Governing Council on October 13, 1943 and is intended to supersede the earlier report.

No data are available concerning the number of health educators employed by schools and colleges.

The committee just mentioned has estimated the need for health educators on the basis of present population groups, health departments, school systems, and voluntary health agencies, to be as follows:

| | |
|---|----------------|
| Local health departments | 1,948 |
| State health departments | 219 |
| Federal health agencies | 40 |
| Voluntary health agencies (all levels) | 2,331 |
| Local school systems (supervisors) | 1,311 to 2,300 |
| State school systems | 48 |
| Federal office of education | 6 |
| Teacher training institutions | 310 |
| | <hr/> 6,213 |

This estimate omits specialists like writers, editors, audio-visual specialists, research analysts, photographers, and librarians, of which health departments were estimated to need 335. It omits also the health teachers, employed or needed in the 29,000 public high schools and other secondary schools and the few hundred in colleges other than teacher training institutions.

These figures as well as the present acute shortage of adequately trained health educators give promise of employment and useful service for the young man or young woman entering the field. Increasing recognition is being given to the importance of the total, unified, community-wide program. Promotional progress may thus be anticipated by the beginning health educator both through the expansion of his program and through transfer to the service of larger population groups, as his ability is demonstrated.

The health educator in the health department works under the administrative leadership and direction of the health officer. The health educator working in the school system as a teacher, coördinator, supervisor, or consultant, is a member of the staff of the school and will, of course, meet whatever professional educational standards are set by the school for the type of work involved. The health educator in a voluntary health agency is employed as a staff member or as executive secretary. A health educator serving the total community may be jointly em-

ployed by health department, school system, and voluntary health agency, or by any combination of them. Joint planning is needed in any community-wide program.

The educational qualifications of the health educator, whether employed by a governmental or by a voluntary agency, should meet generally accepted standards. This report proposes *desirable areas of competence for the community health educator*, based upon the functions which he is expected to perform. The recommendations are made for the guidance both of officials responsible for the appointment of health educators and of individuals looking forward to careers in health education.

The professional standing of persons now performing creditable service as health educators has been established. Successful experience and demonstrated ability should be recognized at the present time as evidence of professional qualifications.

Educational qualifications for health educators working entirely within a school system although needed are not proposed in this report, as the preparation of such qualifications is not a function of this Association. Schools have their own planned and organized program of health education which should be a part of the total community program. Schools are broadening their concepts of their health education responsibilities to include a consideration of home and community, because they find that children cannot practise what they learn at school unless adult customs in the home permit it. At the same time health departments are recognizing that community programs of health education in which schools do not participate have lost much of their potential influence.

Other forces are moving us toward unified community programs. Other groups, like agricultural extension workers, are beginning to incorporate health education in their program.

Voluntary health agencies are finding that sporadic educational programs promoting a single goal may prove to be ill timed, competing, confusing, and ineffective. They are turning to community planning and coöperation.

The recognition that all health educators should concern themselves with the total community program has brought with it a realization of the breadth of training that all health educators need. Health authorities have realized that this public health worker is an educator by profession, that he works with schools and needs training in general education and school health education as well as in public health education.

School authorities have realized that health educators in school systems need instruction in public health and the work of public health agencies as well as in hygiene and the public school procedure. In suggesting the training of the community health educator the committee has in mind that in the absence of a school health educator, he will work with school administrators, supervisors, teachers, and curriculum committees, but that he will not ordinarily supervise classroom teaching. State laws, school authorities, and professional groups in education have set requirements and credentials for teachers and supervisors at various levels. Such standards are not a responsibility of this Association. The committee believes, however, that the health educator who meets such standards in general education and also the qualifications listed below, will have an excellent professional background for school health education.

II. THE FUNCTIONS TO BE CARRIED OUT IN THE TOTAL PROGRAM OF COMMUNITY HEALTH EDUCATION

The following functions are believed to be essential for carrying out complete community-wide programs in health

education. They are not the functions of any one health educator and it is not expected that any one health educator will have special skills in all the knowledge areas involved. Health educators in various positions, however, will be expected to undertake some or all of the following functions or activities which involve the formulation of plans and methods, the application of specific techniques and skills, the supervision of the work of others, and the maintenance of group relations.

The functions of health educators in community-wide programs of health education are:

In accordance with the administrative policy of the health department or other employing agency:

1. To assist in planning and organizing a program of health education of suitable scope and activities to meet adequately the needs of the community, state, or area to be served. This includes, at the outset and continuously thereafter, a study or survey of the needs and resources with the aid of technical experts and the determination of health problems by lay and professional groups.
2. To assist the area to organize for health education.
3. To assist in establishing and maintaining close, coöperative, working relationships between all agencies (official and nonofficial) which may contribute to health education.
4. To aid in stimulating, organizing, and guiding in-service training programs in the field of health, for employed personnel, in accordance with the policy of the agency or institution involved; including:
 - a. Health agency personnel
 - b. School personnel
 - c. Personnel of other agencies
5. To aid, in accordance with the policy of the institution concerned, in planning the health education aspects of pre-service training programs for professional personnel, including: (a) public health personnel, (b) school personnel, and (c) others.
6. To provide consultation and guidance to various individuals and groups (such as Parent-Teacher Associations, service clubs, and others) in developing and improving

the health education aspects of their programs.

7. To assist in promoting, organizing, and guiding study groups in the field of health for adult and group work agencies, such as divisions of adult education or young people's clubs.
8. To contribute to the improvement of the quality of the health education of pupils or students in accordance with the standards and policies of the school system or institution (in the absence of or in coöperation with a school health educator).
 - a. Through aid in planning school health programs and curricula of health instruction
 - b. Through conferences with teachers, supervisors, and school administrators
 - c. Through such other educationally sound activities as the school may desire
9. To assist in stimulating and establishing adequate public health and school health library facilities.
10. To assist in organizing and operating an informational service to provide answers to inquiries; and in answer to requests, to suggest source materials and source references.
11. To be responsible for the preparation, selection, assembly, and distribution of health education materials, using the services of special technicians and health experts whenever possible.

Such materials include:

 - a. Reports and other printed materials
 - b. Visual aids, such as motion pictures, film strips, photographs, graphic materials, exhibits, and posters
 - c. News releases and radio scripts
12. To organize and assist in conducting a speakers' bureau, conferences and meetings.
13. To assist in planning and, in accordance with the policy of the agency, in preparing the health education budget.
14. To encourage, and assist in the development of efficient records and reports of all health education activities in order to facilitate the quantitative analysis, evaluation, and interpretation of the health education program.
15. To assist in the establishment and employment of methods for continual appraisal, in order to evaluate the effectiveness of all phases of the total health education program.

A job analysis of existing positions reveals wide variations in their scope. In general the health educator employed

by a health agency is (1) a director of health education, or (2) a staff member with the title of health educator. Other specialists such as editors, audio-visual specialists, research analysts, photographers, and librarians are commonly employed in the larger agencies.

III. EDUCATIONAL BACKGROUND

The procedure used in determining the desirable educational qualifications here listed, was to analyze each of the above functions in terms of needed professional qualifications in basic sciences, social sciences, and public health, and to group these qualifications in suitable areas.

Certain facts should be borne in mind in approaching this discussion. Not all positions in health education, as indicated above, are of the same scope. The health officer or other appointing authority may not deem it necessary to require all the qualifications listed below for every position. *They are the qualifications believed desirable for the director of a large and complete program.* Nevertheless it is believed that the continuing improvement in the training of health educators will provide more and more workers who have this training, and that such a person will eventually prove most useful.

Experts in various techniques who are not health educators are commonly needed to assist in editorial work and in the development of films, exhibits, and other graphic materials. The health educator concerned with the production of such material will know the nature, limitations, and possibilities of the processes involved. He will know how to work effectively with printers, motion picture producers, and other specialists. This report does not consider the qualifications of these technical experts.

It is clear that the health educator will be helped by a broad cultural background and by a knowledge of (a) the structure, functions, and care of the

body, elements of the more common pathologic processes, and elements of epidemiology and public health procedures; (b) motivation and behavior in human life; (c) society as it is constituted, social forces and their control; (d) forces which affect living-environment and economics; (e) the scientific method in approaching the process of living, distinguishing science from pseudo-science; and (f) the processes of education—why we learn and how we learn.

There is also need for knowledge and skills which are more specifically professional in nature. The division between essentially basic preparation and strictly professional training cannot be readily drawn. It is not the purpose of this committee to indicate here a specific training program in terms of institutions to be attended, degree secured, years of study, or specific courses taken.

Some health educators have begun training for this field immediately upon reaching the university level. More will do so in the future with the increasing number of schools offering an undergraduate health education major.

At the same time it is recognized that several of the professional fields in the health and social sciences, including education, contain many of the elements of training which are desirable for the health educator. Many successful health educators have acquired their training through supplementing the training in one of these professional fields by study in those previously omitted areas of knowledge which are required for health education. It is not feasible to discuss here the entrance into health education from various professional fields. We shall not attempt to define optimal training. We shall attempt to state the essential qualifications.

Present requirements in the training of health educators should be sufficiently flexible to be adapted to the scope of

work required from the individual concerned. There follows a statement of desirable backgrounds and competencies for the health educator, organized under 7 major areas and based upon the duties to be performed in a complete program of health education. The major purpose of this statement is to help those who may wish guidance in preparing for a career in health education. It does not represent recommended minimum criteria for a graduate degree in public health or health education.

1. In the field of *Basic Cultural Education* involving the development of appreciations and skills in the use of the English language, it is assumed that all health educators will have had instruction in English literature, and English composition, and that most health educators will have had some background in general psychology, United States history, and world history.
2. In the *Basic Sciences* it is assumed that all students will have some knowledge of general chemistry, bacteriology, and the structure and function of the human body. Many students will also have had some training in organic chemistry, physics, and biology.
3. Training in *Education and Educational Psychology* is important to provide a knowledge of and functional experience with the learning process, principles and practices of education, methods and possibilities of adult education, the nature of the school health program, educational supervision and administration, and in-service training. It is assumed that all students will have some background in educational psychology and the principles, theory and social aspects of education, as well as professional training and field work in school health education and in public health education, including community organization. Many students will also have had an opportunity to study child growth and development, the elementary and secondary curriculum, and school administration. Some health educators will have had much more extensive study in this field.
4. In the *Social Sciences*, where we are concerned with the racial, social, and cultural characteristics of people and their mores, and the significance of the economic status of population groups, it is assumed that all health educators will have some background in general sociology and that most of them

have some knowledge of political economy and cultural anthropology. If the Health Educator should have come from the social work field, he may have given special attention to comparative religion, social dynamics, and special problems of race relations and of publicity.

5. No health educator can be expected adequately to understand and interpret scientific health facts or the work and program of technical experts and health agencies without sufficient *public health* training to give him a knowledge of basic principles in the organization and administration of public health, personal hygiene (including mental hygiene and nutrition), environmental sanitation, methods of communicable disease control (including the nature of causative organisms and methods of transmission), public health statistics and the principles of statistical reliability, and the nature (not necessarily the skills or technics) of public health laboratory procedures.
6. In *Public Administration*, where we are concerned with governmental and community organization, the nature and functions of community agencies, and principles of planning, all health educators may be expected to have some background in social work agencies and most of them will have had some instruction in the field of government.
7. There are many needed *Special Skills in Health Education*. These include public speaking; the use of methods and materials; evaluation of sources of material and information; the writing of informative and friendly letters; the compilation of bibliographies; filing and clipping methods; the writing and editing of material for publication; the use of the printing and duplicating processes; effective distribution of educational material; the nature, preparation, and use of visual aids; possibilities of community participation in the development of educational material; press relations and technics; the organization and conducting of meetings; technics for the interview and consultative conference; the discovery of leaders and the way to work with them; and the use of group work methods. It is expected that instruction in public health education and school health education supplemented by field work and practical experience added to the background of general education will have provided these special skills at least in some degree.

usually covered at the graduate level. This training furnishes the professional, factual background of the health educator, who will profit by having such instruction presented by specialists, by studying in some of these areas with other public health workers like those with whom he will be professionally associated, and by having his instruction in these rapidly developing sciences just before beginning his professional career.

If the Bachelor's degree is not taken in a teacher training institution, much of the work in education will usually need to be taken after the Bachelor's degree, but it is desirable that most of the work in general education be taken prior to the graduate training in public health and health education. The more highly specialized professional public health courses should not be pushed down into the undergraduate level.

Some colleges and universities are offering a four year undergraduate major leading to a Bachelor's degree in health education. Usually the program is organized through the school of education, and the emphasis is upon *school health education*. This training usually prepares one to become a member of a school staff in the capacity of health teacher or coördinator. Well planned programs of this type serve as a means of supplying more trained people in school health education, and as a valuable reservoir from which to select well qualified students for the graduate training in *community health education*.

At least three months of supervised field work should be required in the training of all health educators. There are advantages in having this field work prior to the completion of graduate training in public health. The prospective student learns the nature of the work and something of his aptitude for it. His professional courses will be more meaningful to him. However, the field work may properly be taken after the

IV. GRADUATE INSTRUCTION

The courses in public health are

completion of the formal courses, before the awarding of the degree.

V. PERSONAL QUALITIES

A candidate for a position as health educator should possess such personal characteristics as creative ability, leadership, good personal health, good judgment, pleasing personal appearance, common sense, and adaptability. Such important characteristics, along with the ability to size up and meet situations, and the ability to present pertinent facts simply and effectively, are not guaranteed by academic records in formal courses of instruction. The health practices of the health educator himself are also important. Study and improvement in methods of determining aptitude of the prospective students for this profession are needed.

VI. LENGTH OF THE TRAINING PERIOD

If one were to enter upon a program of planned study in the first year of university life, this essential training for public health education could not be secured in less than five years. Study beyond this point would be desirable, especially for those aiming for positions of larger responsibility. If such a five year program were followed, the essential basic preparation could be obtained by a four year course leading to a Bachelor's degree in health education or one with major emphasis upon: (1) the basic and health sciences, (2) education and educational psychology, and (3) the social sciences.

The content and extent of the graduate work required would vary according to the amount of undergraduate preparation, the interval between undergraduate and graduate study, and the quality and type of experience the individual has had. But, including the three months of supervised field training, the very minimum of time required for this training would be twelve months following the Bachelor's degree.

From the standpoint of the work to be done, a considerable degree of professional maturity is needed. Usually only one community health educator is employed in a health department or volunteer agency, so that he is responsible for the program rather than being a staff member in his first position. This demand for maturity explains in part why many mature persons have, through further study, transferred to health education from allied fields. If salaries in community health education can be made commensurate with the expanded opportunity for service we may expect to recruit many able students from among the best high school teachers of health or science who have demonstrated interest, aptitude, and ability in developing community activities. There is need for other positions or field opportunities leading toward community health education and from which we may recruit trainees.

In those institutions which offer a doctorate in this field the usual three years of study after the Bachelor's degree are required. Roughly there is one year of study in education, one year in public health, and one year in research.

VII. THE PLACE FOR GRADUATE TRAINING

Most of the accredited schools of public health offer training for community health educators. They offer to the student a staff of experts in public health and health education together with the opportunity to work with students who are entering other specialties in public health. They are the only institutions in which public health training has been standardized. At present these schools cannot accept enough students to meet the need for community health educators. There is urgent need for the expansion of these facilities or the accrediting of graduate courses elsewhere. Certainly they do

not now have room to train (in co-operation with the school of education in the same university) the needed school health educators. It is expected that, for the present at least, most school health educators will be trained in schools of education with special facilities and staff for a curriculum in school health education.

Programs of professional study in health education can best be offered in those institutions which are providing professional education in other fields of public health and which have instructional facilities in the other areas of knowledge required. Field training stations should be available for all students in health education.

COMMITTEE ON PROFESSIONAL EDUCATION

W. P. SHEPARD, M.D., *Chairman*
REGINALD M. ATWATER, M.D., *Secretary*

THE NATIONAL HEALTH ASSEMBLY OF 1948

THE National Health Assembly, which met in Washington on May 1-4, under the chairmanship of Federal Security Administrator Oscar R. Ewing, faced two serious handicaps—shortness of time for preparation of the program and the danger of political repercussions in an election year. These two handicaps were overcome with remarkable success.

Some 850 persons attended the Assembly, representing a wide diversity of professional and public interests; and including the American Public Health Association, the American Medical Association, the American Dental Association, the nursing organizations, the farm groups, the labor unions, the women's clubs, and many more. The object of the Assembly was to outline a program for health advance during the next ten years. It worked through fourteen well organized and active sections covering the needs for professional personnel, for hospital and health center facilities, for medical care, for local health needs, and for research in the health field; and the preparation of programs for maternal and child health, rural health, dental health, mental health, nutrition, environmental sanitation, care of the chronic diseases, rehabilitation and general state and community planning for health.

The reports of the various sections were ably summarized at the closing session by Quincy Howe of CBS (see page 858)—an innovation which might well be followed at similar meetings; and the major resolutions will be made available for the public in printed form. No startling new facts were brought out and no ambitious trails were mapped out for the future. Goals accepted by intelligent public health experts were, however, clarified and buttressed by effectively marshalled evidence indicating the need for increased knowledge of basic facts, better machinery, ampler provision of personnel funds. A few controversial issues, particularly federal compulsory insurance, were recognized as not commanding unanimous support; but the really astonishing thing about the conference was the relatively large area of agreement. The panel on Medical Care, for instance, chaired with the greatest skill and wisdom by Dr. Hugh R. Leavell, unanimously adopted the following recommendations:

1. Adequate medical service for prevention of illness, care and relief of sickness, and promotion of a high level of physical, mental, and social health should be available to all without regard to race, color, creed, residence, or economic status.
2. The principle of contributory health insurance should be the basic method of financing medical

care for the large majority of the American people, in order to remove the burden of unpredictable sickness costs, abolish the economic barrier to adequate medical services and avoid the indignities of a "means test."

3. Health insurance should be accompanied by such use of tax resources as may be necessary to provide additional
 - a. Services to persons or groups for whom special public responsibility is acknowledged and
 - b. Services not available under prepayment or insurance.
4. Voluntary prepayment group health plans, embodying group practice and providing comprehensive service, offer to their members the best of modern medical care. Such plans, furthermore, are the best available means at this time of bringing about improved distribution of medical care, particularly in rural areas.
5. The people have the right to establish voluntary insurance plans on a coöperative basis and legal restrictions upon such right (other than those necessary to assure proper standards and qualifications), now existing in a number of states, should be removed.
6. High standards of service, efficient administration, and reasonable costs require:
 - a. Coördination of the services of physicians, hospitals, and other health agencies in all phases of prevention, diagnosis and treatment;
 - b. Effective coöperation between the providers and the consumers of such services.
7. A medical care program itself will not solve the health problems of the nation. It must be coördinated with all efforts directed toward providing the people with adequate housing, a living wage, continuous productive and creative employment under safe working conditions, satisfying recreation and such other measures as will correct conditions that adversely affect the physical, mental, and social health of the people.

These resolutions—with many adopted by other sections—represent a major step forward along the road to better health for the American people. The endorsement of the principles of group practice and group payment embodied in the resolutions quoted above are almost identical with the recommendations made by the Committee on the Costs of Medical Care in 1932. Their adoption by representatives of the A.M.A., of the Physicians Forum, the C.I.O., and the Cooperatives in 1948—that is something new and something of the first importance. The Health Assembly did not register any dramatic victory over the twin foes of poverty and ignorance; but it did close the ranks of the health army for definite progress in a unified advance toward immediate goals. The Health Assembly was described by one delegate as "Democracy in Action." This was an apt characterization. As a result of these four days the public health worker and his various professional allies have been brought into a closer and more intimate contact with the consumer groups than has ever been accomplished before. The team work developed in the Health Assembly has real promise for the future.

WHAT IS EPIDEMIOLOGY?

SIX years ago,¹ we asked in these columns the question "What and who is an epidemiologist?" The answers were fruitful; but they were necessarily related mainly to the type of practical service rendered by the physicians employed in a health department in tracking down specific epidemics of disease. At that time, W. L. Aycock² suggested that a more vital question would be "What is epidemiology?"

This problem seems specially pertinent today. There are two major lines of approach to the basic theoretical knowledge on which applied epidemiology must be based. One is experimental study in the laboratory—the other observational study in the field. The avenue of laboratory approach has yielded brilliant results, and in recent years has tended to dominate the field. It has distinct advantages. In the laboratory, we can—in large measure—hold all factors constant except the

one we are studying and this makes determination of its influence definite and precise. There is, however, an inevitable disadvantage. The controlled factors may actually be of vital significance in nature; and by their elimination we may reach conclusions which do not at all correspond with the complexity of actual phenomena in the field. Both approaches are essential.

The contributions of field epidemiology were outstanding in earlier days. Snow and Budd had no laboratories; but, long before Pasteur, they laid a firm basis for the epidemiology of cholera and typhoid fever; and they deduced from field observations almost all the properties of those causative factors in these diseases which were later to be observed under the microscope. Hirsch, in his *Handbook of Geographical and Historical Pathology*, understood clearly the relation of malaria, first to "a material and specific poison generated in warm climates and seasons," related to organic decomposition; and, second, to "the degree of atmospheric moisture or of the atmospheric precipitation that results therefrom." He even knew that "wherever malaria is endemic at more or less considerable elevations, the seat of the disease is always a valley with a small declivity or a basin-like depression in a plateau"; and that "we find malaria exceedingly common in small and often definitely circumscribed spots by the sides of lakes, small streams or brooks, pools, ponds and ditches." H. R. Carter, by his field observation of the fact that the vicinity in which a case of yellow fever had occurred became infective only after a period of 2-3 weeks, laid the basis for Reed's conclusive experimental approach at Havana.

Theobald Smith, himself a laboratory experimenter of supreme genius, pointed out that inference from field observation "looks at things in nature, describes and compares them, and deduces from such comparisons certain underlying concepts. The experimental method takes the same phenomenon and tries to check or limit all but one of the activities entering into it so that this one activity can be observed, recorded, measured, and weighed. . . . Both methods have their special advantages and disadvantages . . . the experimental method must not let too many machines get between it and the whole and must find some way of putting the fragment surgically removed for experimental purposes back into the whole"; and "the comparative method is frequently in position to restrain the generalizations deduced from experimental procedures and to keep the experimenter from steering away from the goal, which is an understanding of totality."³

A particular problem has reached the stage of experimental investigation only when field observation or prior experiment has indicated the exact question to be asked. Before each fruitful experiment, there must be a hypothesis; and the formulation of this hypothesis is perhaps the most important and exciting event in scientific thinking. It is courage and vision—checked for fundamental soundness—in developing pregnant hypotheses which seems a somewhat rare quality in present-day epidemiology. W. H. Frost, one of the greatest of all American pioneers in this field said: "Epidemiology is something more than the total of its established facts. It includes their orderly arrangement into chains of inference which extend more or less beyond the bonds of direct observation." To this sort of epidemiological thinking, Ayccock and his group at Harvard have made notable contributions during recent years.

The pitfalls in the path of sound epidemiological thinking are many. We must, first of all, face the fact—obvious but often forgotten—that the entities with which the epidemiologist deals are epidemiological and not clinical in nature. There is no more serious fault in our practical defenses against communicable

disease than our habit of dealing with scarlet fever and septic sore throat and otitis media as different clinical entities (as they are) but not as manifestations of one epidemiological entity, which is the important aspect of truth to the health officer. On the other hand, Aycock⁴ has pointed out that in one clinical disease, Landry's paralysis, the same pathological findings may be due to a wide diversity of causal factors. He suggests the bold hypothesis that—diverse as the so-called causative agents are in this case—they may perhaps operate upon the tissues through the same biochemical mechanism. He cites the extraordinary case of a strange epidemic at Durban, which was considered by various clinicians to be poliomyelitis, and ginger paralysis and tick paralysis and the Guillain-Barré syndrome. It proved on careful epidemiological study to be due to cooking oil contaminated with tri-ortho-cresyl phosphate.⁵ Certainly, where epidemiological phenomena can be reduced to terms of biochemistry (as has been the case with diphtheria and tetanus) the road to practical control will be opened in a startling fashion. Such studies as have recently been made⁶ on the histological reactions of embryonated eggs to influenza virus may perhaps open the way to understanding of the biochemical, as well as the histological, reactions involved.

Our problem is complicated by the splitting up of many so-called "species" of pathogens into serologic "types." Aycock⁷ is skeptical of the importance of such types in comprehending the basic principles involved, although, of course, recognizing their importance in studying a particular epidemic episode. He says that "with the exception of meningococcal meningitis, there is no instance of any degree of correlation between a single serological type and a single disease process."

Even if the chemical processes involved in pathological reactions to an invading germ were identified, it would still be important to realize the complexities involved in the answers given by the human body to the insults offered by foreign invaders. We must never be blinded by the over-simplified conception that we may discover the cause of any disease. The tuberculosis bacillus is not *the* cause of tuberculosis. It is *a* cause of that disease. You cannot have tuberculosis without the *Mycobacterium*; but half the people whose tissues have been invaded by the *Mycobacterium*, as shown by tuberculin tests, suffer from no disease in a clinical form, although they no doubt show minor pathological reactions to the invader.

Inherent "vital resistance" plays an important role in every departure from normality sufficiently marked to be labelled as "disease." We rarely know what this means; but we do know that it means different things in different diseases; and that it is a factor of major importance. Read the accounts of the attempts to climb Mt. Everest and note the different reactions of different individuals to extremes of cold and to fatigue. Study the records of accident-prone industrial employees and accident-prone automobile operators, and realize the important role of neuro-muscular balance in so apparently simple a phenomenon as a mechanical accident. In the clash between a human body and an invading germ, the differences between individuals in the field of biochemistry are equally significant.

Nutrition may be, in many instances, a vital factor in the defensive mechanisms of the body. In this regard, many students of the problem will not agree with Aycock. He concludes⁸ "that vitamin deficiency as a factor in susceptibility to infection is not a general epidemiological principle. The indications are that only deficiencies of certain vitamins affect susceptibility to certain types of infections and that these occur only in limited areas where these vitamin deficiencies reach a sufficiently severe degree to produce tissue changes which are favorable sites for secondary infection." This may be true if the conclusion is limited to

vitamin deficiencies and to the actual process of invasion by pathogens. We doubt, however, whether prevalence of typhus fever in times of famine is due only to poverty and increased infestation with lice (as suggested by Sigerist⁹); and in tuberculosis, the relation of starvation to increased morbidity and mortality seems highly significant.

Perhaps Aycock's most impressive practical contribution to the science of epidemiology lies in his emphasis on the importance of the influence of climate and seasons on the prevalence of disease. It is strange how this relationship has been neglected since research in epidemiology has been limited to the laboratory and has ignored the area of field experience. The winter incidence of upper respiratory infections is the most outstanding challenge in the whole science of epidemiology.

In those diseases which are disseminated by a specific arthropod vector, the influence of season is obvious and clearly recognized. Aycock¹⁰ demonstrates a beautiful case of four widely different seasonal curves for tularemia (with peaks varying from April to November) depending on the particular vector involved. What is commonly ignored, however, is the peak of intestinal diseases in hot climates and seasons and of respiratory infections in cold climates and seasons. It seems clear that in these instances the phenomena cannot be explained by influence on the parasite but must be sought in the physiological status of the human host. The fact that Dick and Schick tests in warm climates show the same infection rate as in cold climates, with an insignificant rate of clinical disease, is proof-positive on this point. North, many years ago, suggested that one very simple factor of seasonal physiologic variation was the relative distribution of blood supply to the intestinal and nasopharyngeal mucosa at different seasons.¹¹ Aycock, in the paper cited above,¹⁰ gives striking examples of seasonal ebbs and flows of physiological status (iodine content of the thyroid gland, organ and gland weights, resistance to acetonitrile poisoning, etc.). In a later communication¹² he presents a striking study of the amplitudes of seasonal fluctuation in various epidemic diseases and reaches the following conclusions: "Three distinct patterns of amplitude of seasonal variation are found in a number of infectious diseases. In upper respiratory bacterial infections as a group, the amplitudes suggest the operation of a single arithmetic variable consistent with seasonal variation in susceptibility. In a second group, comprising diseases transmitted by intermediary means, the amplitudes are consistent with seasonal variation in the virus reservoir. In a third group comprising upper respiratory virus infections, the amplitudes lead to the inference that both seasonal fluctuations in susceptibility of the human being and in the virus reservoir are determinants."

It has been suggested¹³ that the formula for a case of clinical germ disease may be written as follows:

$$A (a_1 a_2 \dots a_x) - B (b_1 b_2 \dots b_x) = C$$

Letting A = the power of the germ to produce disease

$a_1 a_2 \dots a_x$ = various factors increasing the transmissibility (polluted water or milk, flies, mosquitoes, etc.) or the virulence of the germ

B = the power of the human host to resist disease

$b_1 b_2 \dots b_x$ = various factors increasing the resistance of the host (age, specific immunity, nutrition, etc.)

C = a clinical case of a germ disease (or the absence of such a case if the resultant of the factors in the opposite half of the equation falls below zero)

The task of the practical epidemiologist is to concentrate on the weakest links under A (elimination of mosquitoes, pasteurization of milk, purification of water, use of antibiotics, etc.), or on the factors under B which are most easily strengthened (through specific immunization, improved nutrition, personal hygiene and the like). The function of the theoretical epidemiologist is to study all the possible factors in such an equation and to evaluate their relative importance.

THE COBBLER'S CHILDREN

ONE may logically ask why the question of routine chest x-rays for all admissions to general hospitals should be a subject for discussion at this time. The public health significance of a procedure which can be used to determine the presence of disease of the heart or lungs in 16,000,000 hospital admissions annually needs no emphasis. The advantages to patient and hospital staff, the usual findings, the technical methods available, their respective cost, even ways for financing such a program, have all been determined and have been widely publicized.¹ The fact still remains that in 1948 less than 3 per cent of the more than 6,000 hospitals in this country were on record as having adopted x-raying of all admissions as a routine procedure,² despite the fact that about one-fifth of all deaths from tuberculosis occur in general hospitals.

With these considerations in mind, a brief summary of the present status of routine hospital admission x-ray service would seem pertinent. It is generally recognized that a chest x-ray is as important a part of the routine for every hospital patient as a blood count, serology, or urine examination, and will reveal the presence of unsuspected disease more often. Numerous studies have shown that approximately 2 to 3 out of every 100 admissions to general hospitals will have x-ray evidence of tuberculosis. Half of the cases will be active, a rate at least twice that found in the general population. As many more patients will show other types of pulmonary pathology or evidence of cardiac disease. These are individuals already in hospitals, physically and psychologically receptive to treatment. To cure such a patient of a minor infection and discharge him with still undiagnosed active pulmonary tuberculosis is hardly in keeping with the highest traditions of medical care, and certainly in no way consistent with the ideals of public health.

The routine chest x-ray of all admissions to general hospitals serves a no less useful purpose in the protection of the members of the hospital staff. A higher rate of tuberculous infection has been consistently found among doctors, nurses, and attendants in general hospitals as well as tuberculosis hospitals, compared with groups of similar age, sex, and race composition not so employed. The

presumption is strong that the source of their infection may be the patient with undiscovered tuberculosis. Medlar's recent studies³ would certainly lend weight to this hypothesis. The constantly increasing proportion of non-reactors to tuberculin among adolescents and young adults further accentuates the danger of such exposure in hospital personnel. Even if we disregard the important factor of the hospital's human responsibility for the safeguarding of the health of its employees, the desirability of maximum protection for staff in these days of personnel shortage remains. The cost of compensation, which is being awarded in a steadily increasing number of states to hospital employees who contract tuberculosis in the course of their employment, is an additional consideration.

Equally explicit information is available as to technical methods and costs. There is no one method universally applicable to all situations, and the technique to be employed will depend on the daily hospital admission rate and the space and facilities at hand. For larger institutions, with admission rates of more than 25 patients daily, some type of miniature film equipment has been recommended. Full size film is advised for hospitals with fewer daily admissions. The initial outlay for a photo-fluorographic unit is high, \$5,000 to \$12,000, with an overall cost per film of approximately \$.50. Large films can be taken with little or no additional equipment, but each x-ray will be more expensive and an additional burden will be thrown on the technical staff. A satisfactory compromise for institutions admitting approximately 25 patients daily is the magazine cassette,⁴ which has been employed by the chest clinics of the New York City Department of Health since 1943. This unit operates like a roll camera, requiring reloading only once for every 50 exposures. It is rented for a nominal fee and uses full size paper film in rolls of 50, at a cost much less than that of celluloid film. The interpretation of the x-rays, the follow-up examination on suspicious or definite cases of tuberculosis or non-tuberculous disease, and the necessary record keeping present no unusual difficulties, and are readily incorporated into the hospital routine.

The financial problems involved in securing the equipment can be met in several ways. The hospital may pay for the unit itself. In many areas the city or state health department may be willing to furnish the apparatus, particularly if the latter is in a position to utilize federal funds for the purpose. The local tuberculosis and health association, chamber of commerce, hospital auxiliary, or other good friend of the hospital may make such a contribution. Once the unit has been procured, the cost of its operation, which should not exceed \$1 per patient, can be readily met. In private institutions it is usually added to the patient's bill; in public institutions, to the budget.

The most serious drawback to the extension of the practice of routinely x-raying all admissions to general hospitals has been the difficulty in manufacturing photo-fluorographic equipment rapidly enough to meet the demand. Production is now increasing steadily, delays in filling orders are growing shorter, and this explanation will soon be an excuse rather than a reason. Unless the general hospitals of this country are prepared to carry out their responsibility for this program they may find themselves regarded in the same category as the cobbler in the old proverb whose children always had holes in their shoes.

Report to National Health Assembly

QUINCY HOWE

Columbia Broadcasting System, New York, N. Y.

THE following stenotypist's report in the style of a radio commentator was a feature of the final session of the National Health Assembly.

The most human of all human interests has drawn us together here in this National Health Assembly. It is the interest in what most of our forefathers called, and many of us still call, the temple of the soul. After all, nothing affects us more personally and more directly than the health of our bodies.

Human nature has therefore played a big part in all of the section meetings of the National Health Assembly, and it is going to play, I think, a still larger part in the summary that I am to present on the work of these sections.

It is human nature for us to want to help others; it is human nature for us to believe that we are right; it is human nature to make mistakes. I have the layman's admiration for the medical profession. I think our doctors are primarily motivated by the desire to help other people. I suspect some of the rest of us may be motivated by more selfish considerations. But, selfish or unselfish, we are reluctant to believe that we are wrong and that the other fellow may possibly be right.

It is the great achievement of this assembly that so many different experts in so many different fields have reached agreement on so many subjects. Just how correct these agreements may be, we shall perhaps learn before the ten years for which we are planning have run their course.

When Mr. Ewing invited me to summarize your findings, I am sure he

wanted to give you a final reminder that it is human to make mistakes. So far, you have seen human nature at its best. What you are about to hear will remind you how fallible human nature can also be. But perhaps my years with the Columbia Broadcasting system will come to my aid. CBS, you see, makes it a policy not to permit news analysts to go in for special pleading on the air. We are told to present our material in such a way that listeners can draw their own conclusions, so it is in that spirit that I am addressing myself to my present task.

The radio industry seems to operate on the assumption that most Americans no longer know how to read. Perhaps I should say that the radio industry is simply making a valiant effort to make reading quite unnecessary. I am not going to operate on that assumption, though, today. I am going to assume that all of you here, all of you, not only know how to read, but do read. I shall also assume that all of you have read, will read, or at any rate can read the conclusions that the 14 sessions of the National Health Assembly have reached in their reports.

Instead, therefore, of summarizing these reports in detail one by one, reports that speak so eloquently for themselves, let me just point out certain common denominators in these reports, and then single out a few striking specific points in the individual reports.

Finally, I will try to suggest a few broad conclusions that seem to me to arise from this material.

Now, there is one common denominator, a very human common denominator, that struck me with special force in every one of these section reports. It is this: Each section regards its own field as fundamental, basic, all important, indispensable. And in each case, the logic behind these section reports seems to me absolutely unanswerable.

For instance, who can possibly disagree with Dr. William C. Menninger and the Mental Health Section when they tell us that more than half of all our sick people, inside and outside our hospitals, suffer from some kind of mental ailment? No one can dispute the statement of the Dental Health Section, that dental caries, tooth decay, is the costliest disease known in civilized man. Perhaps some of you would like to challenge Dr. Haven Emerson and the Local Health Units Section when they say that our people can't possibly expect to enjoy better health unless and until they organize themselves into more efficient local health units. Certainly he wouldn't find any disagreement from Dr. Florence R. Sabin and the Community Planning Section. They would agree with him when they tell us that the community must do a lot more planning for its own health.

And in another section, you know that the child is father of the man; the mother is the source of all human life, as Dr. Leona Baumgartner and the Maternal and Child Health Section have explained. But to have healthy children, we have got to have healthy and also properly educated grown-ups, and Dr. James R. Miller and his section on the Chronic Disease and the Aging Process explained this when they pointed to the need, the growing need, for better care for our growing generation of old folks.

Then, Mr. Joseph W. Fichter and the Rural Health Section explained why

Americans who live on farms have every reason to consider themselves second-class citizens in so far as medical care is concerned. When you think of that, you wonder about the permanently handicapped and the crippled, veterans and non-veterans, for whom Dr. Henry H. Kessler and the Rehabilitation Section made their appeal.

Then we hear Dr. F. G. Boudreau and the Nutrition Section prove beyond any possibility of doubt that better nutrition is the real answer to better health. Then Mr. Arthur D. Weston, and the section on Environmental Sanitation come along, and they make out an equally unassailable case for better sanitation, purer food, a healthier environment, and, of course, Dr. Algo D. Henderson and the Medical Personnel Section explained the big thing we really need is more and better trained doctors and nurses, and especially assistant personnel. It is also just as true as Dr. Andrew C. Ivy and the Research Section's conclusion that we need more and better advanced research and teaching.

And then Dr. Charles F. Wilinsky, in the Hospital Facilities Section, called attention to the shortage of hospitals and other physical facilities.

Dr. H. R. Leavell in the Medical Care Section perhaps had the toughest assignment of all. He had to get his section to agree on the most controversial single issue before any of the sections: What needs to be done to give the American people the better medical care that they clearly require?

Well, so far I have stressed the differences in all these section reports, but my purpose hasn't been to suggest that they conflict with one another. Rather, I have tried to show how wide a variety of subjects this National Health Assembly has covered. Moreover, it seems to me that the subjects the Assembly has covered do not conflict at all; they overlap. I believe "impinge" is the correct word.

And most of all, they complement and even duplicate each other, complement as well as compliment each other. The need for more and better research, for instance, is a universal need. It goes through all these sections. A good local health unit is going to interest itself in the care of both the young and the aged. It is going to interest itself in mental as well as dental cases; it is going to interest itself in questions of environment as well as questions of nutrition.

Several of these sections have referred to the question of discrimination against Negroes, but discrimination takes many forms, and the best cure for discrimination, after all, is education.

Here we come to what is perhaps the most important single common denominator in all the section reports. Again and again section chairmen pointed out the need for more facts, more research, more information. For instance, how many more doctors, nurses, and medical personnel do we actually need? What do we need in the way of enlarged hospital facilities?

And these questions tie right in with the question of rural health. The Rural Health Section had a lot more information than the section on Mental Health was able to gather. Perhaps that is because we have had country doctors much longer than we have had psychiatrists, but the country doctor is becoming the forgotten man. To the outsider, it might seem the psychiatrist is getting all the breaks, until we read this report on mental health from the Mental Health Section coming up with its urgent request for much more information in a field that is perhaps more tragically understaffed than any other.

Without going into the whole list of section reports and their details—I will do that later—it does seem possible to draw this conclusion now: Nearly all the section reports, as I say, call first and foremost for more information. Surely it ought to be possible to avoid

duplication and to send out (instead of duplicating with similar questionnaires and investigating trips) the kind of questionnaire, and gather the kind of information that could be cleared through some central agency and made available to all the groups.

And such an information center would meet the coöperation of all these different sections before it set up shop in the first place.

Now, the friendly attitude that all the delegates to this Assembly have shown toward one another, the interest all have taken in one another's work, suggests that you can pool your efforts in compiling and then applying the information that almost all of you seem to need.

To most Americans shortages is a wartime word. To you who are fighting a never-ending war of your own against all the ills that flesh is heir to, shortage remains just as familiar a word as ever.

First, there is the shortage of highly trained personnel, of your doctors, researchers, and specialists in lots of different fields. Then there is the shortage of assistants, especially dental assistants and nurses. Then there is the shortage of medical schools and medical teachers, the shortage of hospitals, and, it seems, above all else, a shortage of cash. How are we going to pay for all the training, all the equipment, all the services that we need? How are we going to make the career of administering to the nation's health a career that does not require superhuman effort, superhuman sacrifice, or else a superman's bank account?

Perhaps it is not so much a question of salaries as it is a question of less costly training and of greater security for those who are financially equipped to practise medicine, go in for research, or engage in related fields of public health.

Leaving to one side the controversial question of federal health insurance, there does seem to be a rather wide-

spread feeling in which several sections have unanimously concurred—a widespread feeling that the taxpayer is going to have to carry some, probably more, of the financial burden that better health service requires.

The Rural Health Section, for instance, is unanimously agreed that the federal government must bear a greater share of the expense of rural medical care. The farming communities, even the farming states, just haven't got the funds. On the other hand, the local health units must rely largely, I suppose, upon local support—perhaps through local taxation, somewhat after the fashion of our schools.

But, can local communities carry the whole load of maintaining and extending hospital service? And if the state in addition to the federal government comes into the picture, what part has the state medical association to play? What representation will the public have?

Dr. Andrew C. Ivy's section on the Nation's Need for Research in the Service of Health recommends fluid funds from federal tax sources. No less important than the need for funds is the need for people. The two go together. Get the money and you can get the men.

I am not, as I said, going to summarize all these section reports. All of you can read them as well as I can, and most of you can understand what you read in the field much better than I can.

The section chairmen did me the honor last night of telling me what seemed to them the high points in their reports, and I will now try to pass on to the whole assembly here the salient impressions that these section chairmen left with me.

The most newsworthy and the most controversial decisions were those reached by Dr. Hugh R. Leavell's section on Medical Care. These decisions were newsworthy because of the wide area of new agreement among the members of Dr. Leavell's section.

All the groups represented in this section agree that prepayment is the best way to finance medical care. That means insurance. All agree that all the American people are entitled to medical care. All agree that federal funds must be used to finance at any rate some of this medical care.

All agree—and this is important—that the people have the right to set up their own health insurance plans. As you know, there are more than 20 states that do not now permit this but insist that the medical associations must control those health insurance plans.

This section of Dr. Leavell's on Medical Care even agreed that the medical care program alone will not solve all our health problems. This was almost a unique example of humility among the various sections.

The only disagreement among the members of Dr. Leavell's Medical Care Section—and I am not trying to minimize this disagreement, because it is an important one, but it was there—is the question: How to prepay medical care? How to take out this insurance? Some say that we should continue the voluntary method and give free care only to those who need it—a kind of a means test arrangement. That is the system now in force and that is the system that the committee, I believe, has endorsed. Others however, in this section say that we must have universal compulsory federal health insurance and that that need is immediate and urgent.

Now, for the high points of some of the other section reports. Dr. Algo D. Henderson's section on Medical Personnel stressed particularly the great need for nurses, also the need for dentists, baby doctors, and specialists in mental ailments. The big problem in connection with getting more people into nursing seems to be, as in so many cases it is the big problem, economic. They need, among other things, better working conditions, and the public needs to

know more about the prospects and the possibilities of a nursing career.

Dr. Charles F. Wilinsky's section on Hospital Facilities put a lot of emphasis on the need for coöperation between all and among all different groups and elements in the community. They made the point that our hospital system has got to be kept extremely flexible.

Dr. Wilinsky was pointing out last night that new cures that medical science may develop—like these new penicillin drugs and sulfa drugs that have so much speeded up cure of certain diseases that used to hospitalize people for a long time—may radically change the needs of the American people for hospital care. Most hospitals are still run by private, charitable, and religious organizations, but more tax money is going to be needed to do a better job.

Dr. Haven Emerson's section on Local Health Units came up with about as drastic a suggestion as any. They simply urged doubling all personnel and facilities in the public health schools—just double them! At once! As a matter of fact, there are only nine public health schools now in the United States; only nine. Perhaps that could be doubled. There is a need, in any case, says this section, for basic reorganization.

Dr. James R. Miller's section on Chronic Diseases and Diseases of Old Age wanted to stress two points in particular. First, they wanted to stress the importance of diagnosis of these chronic diseases and early treatment for them. After all, it is to the interest of our children to keep us members of the older generation in good shape and fit so we can work and our kids won't have to support us too soon and too long.

The second point that Dr. Miller's section made is the stress on the importance of rehabilitation. Experience in the rehabilitation of war veterans has shown what can be done in this direction. There is also rehabilitation needed among older people who can be and have

been cured of some of these diseases that used to be fatal.

Dr. Leona Baumgartner's section on Maternal and Child Health included in their report these words: "A child's feeling about a test in school can produce as important a stomach ache as eating a spoiled custard."

This section on child health and maternal care points especially to the recent decrease in the maternal death rate, but it also points out some rather striking figures and facts. Three out of every five children in the United States live in families that have an income of less than \$2,100 a year. Four out of five children live in families that have an income of less than \$3,000 a year. And between Pearl Harbor and VJ-Day almost half a million American babies died as compared with somewhat under 300,000 of our fighting men.

The child health and maternal care section urges and stresses also the need for spending more money on the medical care of secondary school children. The amount of money now spent on those children by the states, through the schools now ranges between one cent per child per year and three dollars per child per year.

And this section tells us that the general public and even, I dare say, many members of this Assembly, don't know what great changes have occurred in this whole field of child care and maternal health.

Mr. Joseph W. Fichter's Rural Health Section reports, among other things, that it is not possible for doctors to practise such good medicine in country districts, simply for the lack of facilities, and yet, on the other hand, this section points out that a lot of Americans would like to go back to country living, and more doctors might be willing to go back to country living if they had the hospital facilities, the money, and the cultural opportunities that the rural communities do not now afford.

Perhaps it is worth while to find out, says this section report, what the small town doctors themselves have to say about the prospects of rural medical care, rural hospitalization, and the rest.

Dr. Ivy's Section on Research in the service of health, stresses two very familiar needs that run like a theme through almost all these reports, the need for more money, the need for more funds to be derived from taxes.

Now, one of the most interesting features of Dr. Ivy's Research Section report was that they agreed that there is no lack of zeal among the bright young students. They want to go in for medical and all kinds of scientific research. This applies in all branches. Research is the thing that tempts and attracts the top 20 per cent, the people with the best scientific minds, and this top 20 per cent, ten years ago and more, used to go into medical research and all other forms of scientific research automatically, but something serious has happened.

The discrepancy between the salaries that one gets as a research worker and the salary that he can get if he is a doctor in private practice, or the salary that he can get as a scientist in the employ of private industry—this discrepancy is so great, and the uncertainty of the future for research is so great, that a lot of these best brains among our researchers are going into other fields.

Like this whole question of rural health, the answer on this matter of research in the service of health seems to me to be looking into all our folkways and seeing if we can't plan our whole lives somewhat differently.

Dr. Sabin's Section on Community Planning urges, among other things, that we take a very broad view and define health, not just as not being sick, but as a wide and general sense of well-being, including social and economic conditions, as well as the physical condition. They also warn against selling

the people in your community the idea of community health and its importance in various projects until you have the personnel to carry these projects through. All the community must participate in these projects. We need more public health councils.

Dr. Henry H. Kessler's Section on Rehabilitation reminds us that we as people are not so husky as we think. We need to know and hear more about the rather high rejection for physical reasons by the armed services during the war, and we need to break down, and this is a long process, the prejudices that exist against crippled and permanently handicapped people.

Dr. Ernest G. Sloman's Dental Health Section stressed especially the need for more dental schools and more dental research. Dental schools, it seems, need \$500 per student in addition to the tuition that the student pays in order to give that student the proper training. The big need here is for research projects—something about dental research—it does not seem as dramatic as in some other fields of research, and yet an awful lot can be done to cut the biggest part of our medical bill, the bill of the dentist, and this dental program ties in with the whole sanitation program because of the possible use of sodium fluoride in drinking water.

Dr. William C. Menninger's Mental Health Section is pioneering in what seems to me perhaps the most important field of any—maybe because it is new. Here are some figures that they come up with: Thirty to 60 per cent of all patients who consult doctors have emotional disorders that lead to physical disorders; 62 per cent of all the inmates of veterans' hospitals are psychiatric patients; one million of all admissions to Army hospitals during the war were psychiatric cases. There is an urgent need for personnel in this field. It is most important to do something about the state hospitals. We have a tendency to forget

about the inmates and the doctors in those hospitals. These doctors number anywhere from one to 300 patients, all the way to one to 1,000 patients—one doctor, one psychiatric doctor to 1,000 patients in a mental hospital, and outside the hospitals there is only one psychiatrist to every 140,000 Americans as compared to one M.D. to every 750. Barely 1 per cent of our practising nurses have psychiatric training, and they have got to care for half of all the patients. One hundred thousand new beds are needed for psychiatric cases in our hospitals at once, and yet with all this need for beds and nurses, prevention is the only real cure to this psychiatric problem, and the prevention of these mental difficulties and diseases and ailments needs the coöperation of every agency in the community—our teachers, our clergy, our lawyers, our social workers, management, labor, and everyone—it is perhaps the biggest educational job there is. It goes, maybe, to the very roots of our whole way of living.

Dr. Frank G. Boudreau's Nutrition Section says there ought to be a nutrition expert included in every health group; that nutrition is the field in which the most striking advances have been made in the last twenty-five years. We ought to start nutrition work on expectant mothers at the very start of pregnancy. Then we will get better children all through life and a lower maternal death rate. And one point that Dr. Boudreau recalled last night was that during the war, in England, Churchill went to his top scientists and said:

"What is it that must come first on the list?" They said: "See that the British people get first-class nutrition during the war." They got that nutrition, and in spite of having fallen back in many, many other fields, and suffered all kinds of hardships and tribulations, the British health, due to this good nutrition, is better than it has ever been before, and a great part of the explanation, the

way the British have told us, is because of the attention they gave to this matter of nutrition.

Mr. Arthur D. Weston's Section on Environmental Sanitation is important because it stresses the external—the importance of external factors in relation to public health.

Now, before summarizing this summary, and drawing one or two final conclusions from the many I have outlined, I think I have a duty to report on one other matter.

As Mr. Ewing explained, this assembly cannot, under the law and under its own rules, recommend any definite legislation. I do not think this prevents me in summarizing these reports and discussions from touching on the question of the membership of the United States in the World Health Organization. Dr. Louis I. Dublin raised the question yesterday from the floor. He did not press his proposed motion to urge Congress to act because Mr. Ewing said it would be out of order. Mr. Ewing made it clear, and I think it was clear to everyone present, that all members of all sections agreed that whatever our other differences may be, we united in wanting the United States to join the World Health Organization.

Dr. Fishbein, of the A.M.A., has already made two strong public statements, though, to that effect here at this assembly, and I have not heard one dissenting voice, and I have heard an awful lot in praise and agreement. For what it may be worth, perhaps I may raise my voice, too, safe in the knowledge at this time, at any rate, that I am expressing something that everybody here feels agreement about.

And this question of the World Health Organization is not the only matter on which this assembly has reached agreement. As I review the high points of the section reports, the high points that the section chairmen wanted stressed, it seemed to me that this assembly has

come to agreement on a great many important matters—matters on which agreement has not always been possible before.

Perhaps the greatest single achievement of this assembly is that all kinds of public organizations have sat down together and worked out common problems and common programs with members of the medical profession and other scientific groups.

Now, some laymen may feel that the American Medical Association has been somewhat slow in coming around to health insurance and to the idea of government aid for health. But look at it from the doctor's point of view: Like all of us, doctors are creatures of habit, and they have acquired their habits in about the hardest way there is. Just try to change some of your own habits. Try to stop smoking the way I did a little while ago; or try pulling up stakes; try going to live in a new community, changing your profession—it isn't easy:

Those of us who have been impatient with the American Medical Association for resisting change show a sad lack, I think, of understanding of human nature. Doctors have to make so many sacrifices. They submit themselves to so many disciplines, they are so overworked just keeping up with their own jobs, that the wonder to me is that any of them have time for anything else. And it is only natural that those who do interest themselves in something beyond their engrossing daily tasks want to hold on to their own tried and tested way of doing things.

That so many doctors not only have taken the time to work with the National Health Assembly but have shown themselves so coöperative, so understanding, so open-minded, seems to me the most promising and the most important development of this whole meeting. The example that the doctors have set us here should encourage all of us to go on with the kind of work that this National

Health Assembly has only just begun.

Now, there is no question that the high spot of this assembly is the coöperation between men of science and the general public. This coöperation reminds us that the atomic bomb and atomic energy are not so new as we have been led to believe. Everyone said when the atomic bomb went off that now we are in a new age, nothing is the same as it was before, and now the scientist is out of his ivory tower, and now science has got to interest itself in politics and general affairs, and the general public has got to be interested in science.

But even if there had been no atomic bomb, we would have had a meeting like this just the same. It is all a part of the same trend. The atomic bomb is one part of it, and this meeting is another part of it. It is the trend of bringing the scientists out of the laboratory, forcing the laymen to concern themselves with the impact of science on our lives. Here it happens to be medical science.

There seems no doubt that medical science can do the job. The two big questions are: Where will the money come from and where will the people come from? This assembly is hopeful. It is a hopeful sign because it is a sign of the times. It proves that the scientists and the public can work together, with government officials acting simply as intermediaries, but with the funds that finance this assembly coming from private sources. It seems almost the ideal combination of government, free enterprise, of expert and layman.

Now, as a complete and rank outsider, can I take advantage of the tolerance of this tolerant gathering to close with just one mildly critical observation, not so much of this National Health Assembly as of our American way of doing things.

As I said at the beginning, all these section reports call for more and more

facts. Of course, none of these sections has yet got the complete story. That will never be told. Some of them are just beginning to pioneer. All of them need to correlate what they already know. But we Americans, as a people, seem to have a blind passion for facts as facts. We have an almost mystical faith in statistics. Now, the collection of facts is a necessary and rewarding enterprise, but it is not a substitute for action. It is not a substitute for something that is even more difficult than action, and that is thought. Too many of us simply collect facts simply to avoid having to do anything about it. We are like the fanatic who redoubles his zeal after he has lost the sight of his objective.

During the 1920's, a wise Spaniard, Salvador de Madariaga, wrote a book, *Englishmen, Frenchmen, and Spaniards*. He made the point that the Englishman is the man of action, the Frenchman the man of thought, the Spaniard the man of passion. The Englishman, he said, thinks with his knees and elbows; he acts on instinct, and he almost always acts right, although he cannot, possibly tell you ahead of time what he is going to do or explain afterward why he has done it. The Frenchman, on the other hand, can give a perfect analysis of every situation, but when the moment to act comes, he is mentally muscle-bound and has a hard time putting his ideas into practice. Afterward, however, he can always give a perfect explanation of just exactly what happened.

Now, if the Englishman is a man of action and the Frenchman is a man of thought, the American seems to me a man of fact. Where the Englishman puts all his energy into action, we put all our energy into collecting data. Where Frenchmen put all their energy into theory and logic, we put all our energy into accumulating facts.

This is not a tendency that is peculiar to science. I think my own field of radio is the worst offender. Have

you ever seen a market survey, a listener's survey, a breakdown of Hooper ratings? I am going to take a chance now. It is no accident that Dr. Stanton, president of the Columbia Broadcasting System, one of the sponsors of this National Health Assembly, is himself a statistician.

Now please do not misunderstand me, and I hope Nate Halpern, Dr. Stanton's deputy at today's session, won't misunderstand me either. All I am saying is that a great many Americans are completely fascinated by facts. Obviously the American radio could not be where it is, and the American science could not be where it is if our leading people in these fields had not devoted themselves to the pursuit of facts, facts, facts.

But I am not saying anything to this assembly that I would not say to the president of the great organization for which I work if I say that the mere accumulation of facts is not an end, an aim in itself. It is what we do with the facts; it is what we make the facts mean that really matters.

I am not going to tell you people what all the facts that your various sections have gathered together mean. I don't know. But I am sure a lot of you do. In some of the fields that your sections have covered you will, of course, want to go out and gather more facts. Rightly! But in other cases I am sure that you have enough facts to spell out some answers; and in still other cases I bet you know the answers already and your next step is to do something about them.

It is not, however, part of my function to tell you what to do or what conclusions to draw. It is my function to review some of the material that has come before you. I will feel I have done my part if what I have said leads you to continue in thought, in action, and in spirit, the many tasks you have set yourselves and our people.

Clearing House on Public Health Salary Information

CALIFORNIA STUDIES LOCAL SALARY TRENDS

THE California State Department of Health, through its Division of Local Health Service and at the request of Local Health Officers of California, has released two salary studies covering full-time professional and technical personnel in local health departments of the state. These studies are as of October 1, 1947, and as of January 1, 1948, respectively. The October study includes 34 local departments, the January one, 32, but only 25 departments are common to both studies. A total of 40 jurisdictions are included in one or both studies.

In no instance were salaries decreased between October, 1947, and January, 1948. For the 25 health officers in both studies actual salaries paid or range of salaries, 13 remained stationary, and 12 increased during the 3 month period. In 5 instances the increases were less than 10 per cent, but in 3 they were more than one-third. The highest monthly salary of \$1,125 remained unchanged.

One more example: of 22 chief sanitarians reported at both dates, salaries of 14 remained stationary; those of 8 increased. The increases were less than 10 per cent in 4 instances, and 11, 16, 27, and 41 per cent respectively, in the remaining 4. A detailed study of this material might well reveal that variations in the extent to which salaries were increased among the separate professional groups, bear a close relation to the separate pressures brought upon them to accept other positions.

The relationship between health officers' salaries and the populations of

their jurisdictions is also worth examining. Of the 40 jurisdictions reporting salaries for either October or January or both, 13 had 1940 populations of less than 50,000; in 8 of these the health officer's monthly salary was \$600 or more. Of the 10 whose salaries were less than \$600, 5 served small populations, but 5 served populations of from 50,000 to 250,000. Again it is difficult to sort out exact correlations, particularly in view of the erratic population changes in California since 1940. Nevertheless, these figures bear careful analysis in the development of criteria for setting salary scales. They also pose the perennial question of whether the best use is currently being made of the professional and administrative skills of the public health officer in a population of 30,000, for example.

Perhaps one more word needs to be said. California is among the more fortunate states in having a comparatively low vacancy rate in its local health officer positions, the fruit, in part, perhaps, of such current studies.

LOCAL HEALTH DEPARTMENT SALARY STUDY

The *May Journal* (p. 714) reported a plan to include a sampling of local health departments in the next study of public health salaries. This study, sponsored by the Association of State and Territorial Health Officers, is already under way. The questionnaires have been prepared and sent out by the Committee on Professional Education; the technical work of analyzing and tabulating the material is being undertaken by the U. S. Public Health Service.

Questionnaires have gone to a ran-

dom sample of 126 jurisdictions in 39 states representing all areas of the country. One-fifth of the jurisdictions are state health districts. The study is limited to health departments serving from 50,000 to 250,000 persons.

LOUISIANA TAKES STOCK OF ITS SALARY SITUATION

In January, 1948, the Louisiana State Health Department made a telegram survey of salaries for 30 classes of positions common to state health agencies. Nearly every state replied to the Louisiana questionnaire; the largest number reporting for any category of workers was 43 for director of public health nursing; 42 reported on the director of public health engineering.

Except for the state health officer, salaries in the upper grades of positions appear to be somewhat higher in Louisiana than the average for all states; in the lower grades of positions, they are distinctly lower. For instance, Louisiana ranks 9th among 23 grades of minimum salaries for director of local health administration in 37 states, and 6th in 27 grades of maximum salaries for this position. For public health physicians at the entrance level it ranks 18 among 21 grades of minimum salaries in 28 states, and 14 among 23 grades of maximum salaries.

This study is available from Dan S. Moore, State Director of Personnel, Louisiana Civil Service Commission, Capitol Annex, Baton Rouge 4, La.

CONVINCING A BOARD OF ESTIMATE

In New York City the district health officers of the Department of Health have organized themselves into a Health Officers Council. This organization is

similar to the Conference of Local Health Officers of a number of states.

In April, this Health Officers Council presented a memorandum on salaries to the New York City Board of Estimate. This memorandum pointed out that of 21 health centers covering the 31 health districts of the city, only 13 were administered by health officers qualified according to Civil Service standards; of the 13 only 8 had health department experience. It also pointed out that 8 experienced health officers had left the department in 1947; of 12 carefully selected candidates who received a year's training in a school of public health through federal funds and several months of intensive training in the department, only 5 remained.

The Health Officers Council cites these facts as illustrations of the situation existing with respect to all types of workers in the health department. It believes that the unfavorable salary situation is the basic reason for the failure to maintain department personnel up to strength.

By way of highlighting its argument, the Health Officers Council compares the salaries and the population served of the New York City district health officers with those of 8 neighboring urban areas in New York State and with 10 health jurisdictions in California. This state was chosen because figures were available and because California and New York State are comparable as to per capita wealth.

This memorandum might have suggestions for other areas in their dealings with appropriating bodies. A limited supply of the memorandum is available from the Health Officers Council, 125 Worth St., New York, N. Y.

SANITARY ENGINEERING AND NATIONAL SECURITY

"A Preliminary Report — Sanitary Engineering Aspects of National Security" by the Subcommittee on Sanitary Engineering Aspects of Major Catastrophes of the National Research Council, has now been made available for general study. Prepared for and at the request of the Committee on Sanitary Engineering and Environment of the Division of Medical Sciences of the National Research Council. The Introduction states:

"This report deals with some of the sanitary engineering aspects of major catastrophes primarily as affecting the civilian population. It presents statistical data concerning catastrophes during the last quarter of a century resulting from natural phenomena and man-made causes. It gives emphasis to the special hazards of the future in the light of technological developments in the arts of peace and war and recommends organization of sanitary engineering services to mitigate the effect of future catastrophes and to provide for control and relief measures when they do occur."

"We must make adequate preparations for meeting the emergency sanitary engineering problems associated with natural catastrophes; in addition it is necessary to develop an organization capable of orientation to the contingency of war, while functioning efficiently in times of peace."

The report points out that a well coordinated program of national security to safeguard public health, welfare and our economic potential should include a plan and organization for sanitary engineering activities. The scope of the activities applies particularly to protection and promotion of public health through control measures over the environment in which people live and work. This specialized service and responsibility includes such essential community or regional facilities or services as: water supply, sewerage, control over atmospheric and stream pollution, insect and rodent control, sanitation of food production, processing and distri-

bution, garbage and refuse collection and disposal, sanitation as related to housing, industry, ventilation, swimming and bathing and general community life, and related matters.

Examples of the type of catastrophe in which sanitary and public health engineering play an important role include the general economic prostration which occurred in England during the winter of 1946-1947 due to the unusual snow storms, high winds and floods; the widespread floods which occur in the Missouri and Mississippi River valleys; and the recent Texas City explosion. The committee has classified possible disastrous events into 3 categories: those of natural phenomena such as floods, tidal waves and earthquakes; the man-made accidents which would include explosions, fires, and epidemics; and war hazards, including aerial warfare, atomic bombing, sabotage, and destruction or deterioration of essential civilian facilities.

In the past, the American Red Cross is cited as being the principal disaster relief organization on a national level. According to the report, for the 26 years from July 1, 1920, to June 30, 1946, \$105,000,000 were spent by the A. R. C. in giving disaster relief. Statistical data on the major disasters during that period are included in a separate table. Another tabulation to show the seriousness of major disasters in the United States includes 38 instances during the period 1865-1945 in which a total death toll of 29,622 is listed. A summary and classification prepared by the Metropolitan Life Insurance Company showed that 919 catastrophic accidents occurred during the period, 1937-1946, and listed 12,987 deaths. Data on these events are likewise covered in a special table.

Recommendations include:

"Calamities due to natural phenomena or man-made accidents, or those resulting from acts of warfare such as direct enemy attack or sabotage, involve a wide range of sanitary engineering problems. A consideration of these basic factors indicates that planning for prevention and control over major disasters should originate at a high federal level and be worked out in such detail as to reach down to each community in the nation."

Specific recommendations include:

1. Considering the importance of environmental sanitation in disaster relief work and national security, the committee recommends that special provision be made to develop sanitary engineering programs within the national disaster relief and security program and to place responsibility for them in qualified sanitary engineers.
2. The committee recommends that, in all research and development work of the federal government, channels be established through which the point of view of the sanitary engineer may be obtained. This may be done through employment of qualified consultants or the appointment of one or more full-time sanitary engineers on the staff of the agency or agencies concerned. Agencies in particular need of the full-time services of sanitary engineers are:

American Red Cross
Atomic Energy Commission
Central Intelligence Agency
National Security Resources Board

3. The Sanitary Engineering Division of the Public Health Service, by reason of its specially trained staff and established relationship with the sanitary engineering divisions of state, county, and local departments of health, is particularly well qualified to serve as a liaison unit between federal agencies and those of the respective states and their instrumentalities.

4. The committee recommends that a permanent sanitary engineering unit should be organized in the Public Health Service to carry out disaster and national security activities.

Working with the National Security Council, Central Intelligence Agency, National Security Resources Board, the National Military Establishment, the American Red Cross and various other federal, state, and local agencies, this unit would perform such functions as:

- a. Coördinate sanitary engineering work between federal, state, and local agencies, with special emphasis on mitigation of hazards to civilians in times of peace or war.
- b. Develop plans in consultation with an overall agency, for the organization and mobilization of sanitary engineers, water works operators, and related man power for service in local, regional, or national emergencies.
- c. Promote civilian defense and disaster-relief planning, involving sanitary engineering and environmental sanitation, through the chief sanitary engineers of the state departments of health.
- d. Develop a system of liaison and intelligence whereby in the location, design, construction, and operation of public facilities the interests of national security are taken into adequate consideration.
- e. Alert state and local agencies of such national defense programs as are likely to affect community resources or facilities for which they are responsible.
- f. Develop training programs in environmental sanitation for professional and sub-professional people in order to establish a reservoir of trained personnel for service in times of disorder.

Abel Wolman is chairman of the Committee on Sanitary Engineering and Environment. The Subcommittee on Sanitary Engineering Aspects of Major Catastrophes is composed of Arthur E. Gorman, Chairman, Gerald E. Arnold, Anselmo F. Dappert, Victor M. Ehlers, H. H. Gerstein.

The full report appears in the June, 1948, issue of the *Journal of the New England Water Works Association*, George C. Houser, Editor, Boston 8, Mass.

SCHOOLS OF PUBLIC HEALTH ACCREDITED FOR THE M.P.H. AND Dr.P.H. DEGREES FOR 1948-1949

On April 30, 1948, the Executive Board of the American Public Health Association received the recommendation of the Committee on Professional

Education to accredit ten schools of public health for the Master of Public Health Degree (M.P.H. in the United States; the equivalent degree in Canada

is the Diploma of Public Health or D.P.H.). The Committee on Professional Education also had recommended accreditation of seven schools for the Doctor of Public Health Degree (Dr.P.H.) for the academic year 1948-1949.

The Executive Board voted to accredit these schools all of which had been accredited previously. A reduction of the number of accredited schools

from eleven in 1947-1948 to ten in 1948-1949, is due to a withdrawal of Vanderbilt University which, because of economic circumstances, is forced to discontinue the postgraduate public health training program for the present.

Below are listed the schools accredited for 1948-1949, the degrees for which they are accredited, and the names of the directors or deans.

Institutions Accredited by the American Public Health Association To Give the Degree of Master of Public Health (Diploma of Public Health in Canada) and Doctor of Public Health for the Academic Year 1948-1949

NEW YORK PLANS NEW PUBLICATIONS

With the advent of Herman Hilleboe, M.D., as Health Commissioner, and Granville W. Larimore, M.D., as Director of Public Health Education, the New York State Health Department has taken a look at its weekly *Health News* and come up with plans for a weekly, a monthly, and a quarterly.

Beginning in June, *Health News* becomes a monthly publication, beamed primarily to professional health workers, and applying the principles of community organization. Its first developmental issue of April gave news about the State Medical Society and a number of voluntary health agencies, as well as an article on local health services. It was liberally illustrated with pictures, which is a part of the plan, and produced with a high grade of paper and typography. A wide distribution is planned for this publication.

The weekly publication will be the *Bulletin*, reproduced by multilith, and will have "house-organ" type of material and current communicable disease and other information of interest to public health workers. It started publication in June. The *Quarterly* will be devoted to scientific articles. Both the *Bulletin* and the *Quarterly* will be distributed to professional public health workers only.

WHAT DOES A HEALTH DEPARTMENT DO?

Perhaps a new way of answering this question has been found by the Lawrence County (Illinois) Medical Society. In a folded flier it lists each staff member of the Lawrence-Wabash bi-county health department and reproduces the exact record of what each did during one day.

The health officer of this bi-county

unit serving a population of about 35,000 is Dale E. Scholz, M.D.

THE SAFETY WORLD GETS TOGETHER

In February, 1948, the National Conference on Home Safety, originally organized in January, 1946, was dissolved. At the same time its successor, the Home Safety Conference of the National Safety Conference was born and will assume some of the aims and activities of the former organization. Among the notable achievements of the Conference during the two years of its existence was the publication and wide distribution of "A Man's Castle," an excellent home safety health education tool.

Donald B. Armstrong, M.D., who was Chairman of the Executive Committee of the earlier conference is temporary chairman of the new conference, and chairman of its Steering Committee. The next meeting of the conference will be held in connection with the 36th National Safety Congress in Chicago, October 18-22.

"IT'S IN THE BAG" A NEW FILM

The Texas State Health Department has recently released "It's In the Bag," a motion picture describing the nursing bag technique and an accompanying script. It is intended to arouse interest in high school girls in the public health nursing professions, as an aid in nursing training, as a means of getting certain health information to the public, and acquainting lay and professional groups with public health nursing service.

Details available from Texas State Health Department, Austin 2, Tex.

WORLD HEALTH ORGANIZATION

UP TO DATE

The March issue of *International*

Conciliation (Carnegie Endowment for International Peace, 405 West 117 St., New York 17) is devoted to an article on the Program and Accomplishments of the World Health Organization by Professor C.-E. A. Winslow, with an introduction by Brock Chisholm, M.D., Executive Secretary of the Interim Commission, World Health Organization. Professor Winslow's article is a down to earth summary of the various areas in which WHO operates and the machinery which it employs, but in summarizing he makes the reader see also the wide horizons. This should be in the working library of every public health worker and particularly should it be read by the members of the House Rules Committee, that Committee which on March 12 tabled the resolution for United States ratification of the WHO constitution.

INDIANA MEANS IT

The February issue of the *Monthly Bulletin of the Indiana State Board of Health* is devoted primarily to promoting full-time local health services in Indiana. Its opening article on this subject is illustrated with a cartoon of racers entitled "Come On Indiana," and informs its readers that only 5 states ran behind Indiana in the race for complete state coverage with full-time health departments. There are articles by the executives of the Indiana Tuberculosis Association and the Indiana Congress of Parents and Teachers, and excerpts from the paper by George J. Nelbach of the New York State Committee on Tuberculosis and Health given at the Princeton Conference on Local Health Units. Ten counties are listed as the most likely candidates for supporting full-time service. If they should move over, in fact, from candidates to elected status, 50 per cent of Indiana's population would be covered by full-time local health service.

SCHOOL HEALTH IS GOING PLACES IN WISCONSIN

About 3 years ago in Wisconsin a committee became interested in school health services in that state. Under the sponsorship of the departments of health and education a Wisconsin Co-operative School Health Program with the aim of "better health for every child in the state" was set up.

The program has now prepared a series of 10 *Guides for Better School Health*. No. 1 is *The Road to School Health* (see *January Journal*, p. 119), and No. 10 is *Nutrition Education for Boys and Girls*. In between are pamphlets on school water supply, heating and ventilation, lighting maintenance, dental health, tuberculosis health education, school health examinations, health and safety instruction, and nutrition education. All of these bulletins are available on request from the State Department of Public Instruction, Madison.

The program has been under the direction of Warren H. Southworth, Associate Professor of Education of the University of Wisconsin. Many persons and many agencies have coöperated; 5 of the bulletins were published by the State Department of Instruction, 2 of them with funds supplied by the W. K. Kellogg Foundation; 2 by the State Board of Health, and 1 each by the Department of Agriculture and the Wisconsin Anti-tuberculosis Society.

This coöperative program has also had an annual school health conference. The report of the third one, held in October, 1947, is now also available.

MENTAL HEALTH ON THE RADIO

An exciting new series of 13 transcribed dramas on mental health, *The Tenth Man*, was recently released by the National Mental Health Foundation and is now available for sponsorship on local radio outlets or for other educational uses. Designed as tools for local mental

health societies, doctors, social workers, and others who wish to inform the public about psychiatric facts, these 15-minute radio plays dramatize some of the problems of the one man in 10 who needs or will need professional care for a mental or nervous disorder. The series has received commendation and endorsement from the Group for the Advancement of Psychiatry and the United States Public Health Service. Ralph Bellamy, noted actor, appears as narrator throughout the series, and prominent radio actors play supporting roles. For further information write to the National Mental Health Foundation, 1520 Race Street, Philadelphia 2, Pa.

THE IDEA WAS GOOD ANYWAY

The Lorain County (Ohio) Health Department held its 28th annual meeting on March 1. It celebrated, among other things, a \$35,000 two year grant from the W. K. Kellogg Foundation to establish a rural field training center for public health personnel.

Worthy of special mention, however, is its attempt to use the occasion to publicize rural health service over a wide area. It invited *Life Magazine* "to go to an annual meeting of a rural health department" giving as background material some of the facts from *Local Health Units for the Nation*, as well as some indication of the critical personnel shortage.

That *Life* did not accept the invitation, makes it no less good an idea. It takes more than one try to land in big time popular magazines.

MAYORS KNOW THE COST OF SLUMS

The United States Conference of Mayors publishes *America Cannot Afford Slums*, a graphic story in pictures and charts of the increasing financial burden and growing social problem of slums. It is designed as an argument for the Taft-Ellendorf-Wagner housing

bill. This telling argument for the bill is attractively packaged in a well printed, well illustrated booklet in pleasing colors.

HOUSES ARE HOMES

The Woman's Foundation has just published *Houses for Family Living*, a summary of the ideas discussed at the Rye, N. Y., Conference on Housing for Family Living in November, 1946. The stated purpose of the pamphlet is "an attempt to put between two covers some of the information recently acquired on family living and the home and to think through what it means." This excellent technical production is available from the Woman's Foundation, Inc., 10 East 40 Street, New York 16, N. Y., 35 cents—less in quantity orders.

It will be remembered that the Woman's Foundation initiated the chain of events that culminated in the National Conference on Family Life held in Washington, D. C., in May, 1948.

STREAM POLLUTION ABATEMENT

The *Annual Report—Interstate Sanitation Commission* for 1947 gives a record of the accomplishments of the tri-state body organized by New York, New Jersey, and Connecticut to control pollution of the greater New York bay area. Willing coöperation on the part of industry and municipalities is reported, although recourse to the legal powers of the Commission was resorted to 13 times in 1947 through issuance of orders on uncoöperative municipalities or industries. An increase in time spent in meeting requests for special services is noted as a result of continued public education. Among special activities followed was a continued participation in studies of the prevalence of marine borers, studies of storm water infiltration and storm-flow by-passing at sewage treatment plants. Results of chemical and bacteriological tests of samples taken from the various sewage

contributors in the area are presented for the years 1945, 1946, and 1947.

INTRODUCING THE TUBERCULOSIS HOSPITAL

Among the problems of a tuberculosis control program is the natural reluctance of the sufferer's family to hospitalize him away from the home and the nameless fear of hospitals that still remains in many areas. With this in mind the New York State Committee on Tuberculosis and Public Health has published, in an attractive illustrated booklet, *Your Sunnount*, subtitled, "Veterans Administration Hospital and How It Serves You."

The booklet is written for the patient and his family and describes the facilities for his cure and rehabilitation. In the process a good deal of tuberculosis health education is included. This description of a veterans' hospital in New York State to increase effective hospitalization of tuberculous veterans might well be copied elsewhere.

NLNE LEAGUE LETTER

Under date of March 5, the first *League Letter* of the National League of Nursing Education appeared. This is one of a series planned by the NLNE Committee of Public Relations to bring "brief, prompt, accurate information to state and local leagues about happenings in nursing education." Available from NLNE, 1790 Broadway, New York 19, N. Y., at 10 centes each.

A closely related publication is the *News Letter* of the Committee on the Structure of National Nursing Organizations, Volume 1, No. 1, which was issued in March. It is to be "published occasionally" and addressed to every member of the 6 national nursing organizations represented on the Committee on Structure numbering over 200,000. Available without charge from Room 201, 1790 Broadway, New York 19, N. Y.

TELLING DOCTORS ABOUT THE NATIONAL HEALTH COUNCIL

The *New England Journal of Medicine* for January 15, 1948, editorializes on the subject of Voluntary Health Agencies and the National Health Council. This outlines the services the National Health Council can give to existing health agencies. It suggests also that the American Medical Association again become a member of the Council.

The editorial is particularly valuable in interpreting for physicians and local medical societies the Council and its activities in developing local health councils. It has been reprinted by and is available in limited quantities from The National Health Council, 1790 Broadway, New York 19.

ANNUAL REPORTS

Twentieth Anniversary Annual Report, Georgia Warm Springs Foundation, is worth a few minutes for many reasons: to remind us of the physical courage and tenacity of the late President, for the information about the Foundation it contains, especially as to its growth in 20 years, and finally for the technical excellence of the pamphlet itself.

A Summary Report, Food Supply Division, The Institute of Inter-American Affairs, 1942-1947. If you want to know some of the long range attacks on bad health in Central and South America by way of soil conservation, better milk production, use of fertilizer, varied garden crops, leaf through this attractive report with its pictures.

Annual Report of the Social Science Research Council, 1946-1947, is the story of one organization's contribution to the knowledge of human relation through research. It deems its first task in research to be planning, that is, "the entire process of developing research personnel, improving techniques, mapping opportunities and needs, designing

projects, assuring the existence of proper materials, encouraging the investment of funds in research, and better the circumstances under which research is conducted."

Donald Young was the Director of the National Research Council during the period of this report. He is now General Director of the Russell Sage Foundation. His successor at the National Research Council is Pendleton Herring, formerly of the Carnegie Corporation of America and Professor of Government at Harvard University.

The offices of the Council are at 230 Park Avenue, New York 17.

WORTH ACQUIRING

Born Thirty Days Too Soon! was prepared by the Maternal and Child Health Division of the Kansas State Board of Health (Topeka) on behalf of the premature baby because he is too tiny to plead his own case. This tells the simple facts about prematurity, the facilities available, and a plea for tax money of eight cents per capita to expand the program, as well as suggestions for setting up a community program. It gives a page of pictures of great men who were premature babies—Winston Churchill, Darwin, Voltaire, and others.

Good News About Diabetes is number 138 in the series of Public Affairs Pamphlets and explains that the life expectancy of the diabetic is constantly increasing if he pays more attention to his health than the average non-diabetic. The author, Herbert Yahraes, also reports on the activities of the American Diabetes Association and the Diabetes Section of the U. S. Public Health Service, and urges increased funds for research, particularly into the why of diabetes. Public Affairs Committee, 22 East 38 St., New York 16, N. Y., Room 204.

The Unexpected Gift is one of a series of science readers for junior high school. This one, in story form, tells about a well balanced diet and how a school lunch program may be developed. Project in Applied Economics, College of Education, University of Florida, Gainesville, 35 cents, or 28 cents in orders of 25 or more.

The Problem of Cerebral Palsy by Meyer A. Perlstein, M.D., with the assistance of William McPeak, social science analyst, has been published by the National Society for Crippled Children and Adults. It is designed as "an aid to the medical profession, for leaders in community organizations, and as a guide to workers in the fields of health and rehabilitation." Included is a description of the problem of the cerebral palsied child, a suggested state program, professional training, research needs, and cerebral palsy as a socioeconomic problem. There is a diagrammatic chart of how a model cerebral palsy program operates, and some hypothetical case histories illustrating the mechanics of the cerebral palsy program.

Available from the National Society for Crippled Children and Adults, Inc., 11 S. La Salle Street, Chicago 3, 25 cents.

State Administration of School Health, Physical Education and Recreation is a status study by the U. S. Office of Education. It gives the current legal and administrative provisions in the various states for the development of school programs of health, physical education and recreation. One section is devoted to coöperative arrangements between state departments of health and education.

Available from U. S. Government Printing Office, Washington 25, D. C., 15 cents.

Public Health in Foreign Periodicals

GEORGE ROSEN, M.D., PH.D.

DURING World War II, it was realized that a complete and accurate study of the influence of the war and of war conditions on public health would not become possible until the end of hostilities.¹ When the fighting ceased, public health workers in various countries began to survey the situation. Attention was turned to the problems of infant mortality, tuberculosis, venereal disease, and nutrition, that is, those problems that were found to be most pressing. So far, information has become available only in piecemeal form, relating to individual countries or to specific restricted problems. At the same time, new problems have not been neglected. In illustration of these comments, a number of investigations dealing with European countries have been selected for review.²

INFANT MORTALITY IN FRANCE

In France, the natural decrease of population already existing prior to the war was accelerated during the war years. French authors are, therefore, inquiring into the problem of infant mortality. Lesné and Debré point out that infant mortality, which had steadily declined during the years preceding the war, in 1940 showed an abrupt and considerable rise. From a rate of 110 per 1,000 live births in 1914, infant mortality had fallen to 64 in 1939. As a result, however, of conditions arising from the war and the occupation, e.g., the exodus in the summer of 1940, food difficulties, and infections, infant mortality rose to 91 in 1940, dropped to 77 in 1944, and reached 102 in 1945. It should be recalled that this was the severe winter of 1944-1945 when there

was great scarcity of food and fuel. In 1946, however, throughout France there was a sharp drop in infant mortality. The rate for France as a whole was 70 per 1,000 live births.

The authors state that about 100,000 infants under 1 year of age die annually in France. The highest infant death rate occurs before the age of 3 months; and approximately one-third of all deaths under 1 year fall under the heading of neonatal mortality. These deaths are due to various pathological conditions, and to biological, social, and economic causes. Lesné and Debré are more concerned about the latter, for it is their contention that attention to the social and economic problems could save for France three-quarters of the infants who die before the age of 1 year.

The problem of breastfeeding is considered at length. Intensification of the campaign for breastfeeding is advocated. This involves education of doctors and midwives, as well as the general public in the value of breastfeeding. Economic assistance and extra rations should be provided for every nursing mother obliged to work. Breast-milk depots should be established in every large town. Ignorance, carelessness, and poor home conditions contribute to a high infant mortality. Alleviation of these conditions requires a combination of the efforts of doctors and social workers, and an improvement in economic conditions. Furthermore, families with young children should have a priority of fuel. Finally, the authors emphasize the necessity for periodic medical supervision during pregnancy, and during the first year of life. Prenatal clinics and infant

consultation centers must constantly carry on a campaign of education with mothers.

MORTALITY AND MORBIDITY IN DENMARK DURING RECENT YEARS

A survey of public health conditions in Denmark during 1946 presents an interesting comparison with conditions preceding and during the war.⁴ The general mortality rates recorded in Denmark are lower than those observed before the war. The years 1942 and 1943 were record years, with the mortality rate dropping to a low of 9.6 per 1,000 population. Tuberculosis mortality is a sensitive index of prevailing social and economic conditions, especially the factors of nutrition and work. War, influencing as it does both of these factors, might be expected to result in a significant increase in tuberculosis mortality. Such was not the case in Denmark. The pre-war downward trend of tuberculosis mortality was checked at first, but was later stabilized. At present, the trend is again downward. During the period 1936-1940, the tuberculosis mortality rate was 40 per 100,000, whereas in the period 1941-1945, it dropped to 34 per 100,000. In 1945, the tuberculosis mortality rate was the lowest yet recorded. It is reported that deaths from all forms of tuberculosis, both pulmonary and other, were even less numerous in 1946 than in 1945.

On the other hand, the war exerted an unfavorable influence on the incidence of typhus fever, typhoid fever, dysentery, scabies, syphilis and gonorrhea. The incidence of scabies achieved a record peak in 1945. Venereal diseases spread considerably after the beginning of the war. Syphilis is reported to have been eight times more frequent in 1944 than in 1940. The number of cases of syphilis reported for these two years was 4,053 and 485 respectively. The trend with respect to gonorrhea was similar. From 1940 to 1944 the incidence of

the disease is reported to have increased threefold. The peak incidence for gonorrhea was reached in 1945. During the war there was also a rise in the mortality rate from heart disease.

BCG VACCINATION IN SWEDEN AND RUSSIA

Among the problems remaining in the wake of the war, tuberculosis occupies a prominent place. In dealing with this problem many countries are today using BCG vaccination.

The use of the Calmette vaccine in Sweden dates back to 1925 when the first trials were carried out by the oral route.⁵ Intradermal introduction of the BCG vaccine was first employed in 1927 at a children's hospital in Gothenburg, and has since been the preferred mode of administration. During the succeeding two decades the number of persons vaccinated has increased progressively. By the beginning of 1947, 500,000 persons had been vaccinated at least once. The progress of this movement has been promoted by the coöperation of governmental organizations and voluntary agencies. The Swedish National Association Against Tuberculosis has played a leading role in these developments.

Russia, too, has made extensive use of BCG.⁶ The Soviet Union was one of the first countries to undertake the study of the Calmette vaccine. In 1924, Tarashevich at Kiev received a culture from Calmette's laboratory at Paris. Belonovsky at Leningrad received a second one in 1926. After a period of preliminary studies, the first vaccinations were carried out in 1926 in the Ukraine. In 1928, vaccination was started in Leningrad, and a year later, the operation was extended to cover five large cities (Leningrad, Moscow, Saratov, Kazan, and Rostov on the Don). It was not until 1937, however, that a widespread movement was started. This movement continued even during the war. By 1940, more than two million

infants had been vaccinated. In the majority of cases the oral route has been used for vaccination. A small number of infants have been vaccinated subcutaneously.

HEMORRHAGIC FEVER IN THE CRIMEA

The Russians have also been active in the field of medical parasitology.⁷ In the spring and summer of 1944 and 1945, a mysterious hemorrhagic fever prevailed, often with fatal results among farmers and peasants in the Crimea. Investigation by a group of scientists showed that this disease was caused by a virus transmitted by the tick, *Hyalomma marginatum* Koch.

Grobov studied the local fauna in order to establish possible reservoirs of infection. After investigating various rodents, he found that only hares (*Lepus europaeus transsylvanicus*) harbor the larvae and nymphs in large numbers.

When the nymphs mature in the spring, they bite cattle and human beings, in this way transmitting the disease. The author suggests that birds may also play a role in the transmission of this fever, since nymphs of *H. marginatum* were found on several avian species.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Applied Medical Bacteriology—
By Max S. Marshall, with the collaboration of Janet B. Gunnison, Alfred S. Lazarus, Elizabeth Morrison, and Marian C. Shevsky. Philadelphia: Lea and Febiger, 1947. 340 pp. Price, \$4.50.

It is a pleasure to review a book whose title so aptly describes its contents. The authors have succeeded in presenting an amazing amount of information in 340 pages, in a clear, concise, and well organized manner. The method of approach conveys the practical aspects of medical bacteriology as applied to and used by clinicians, public health workers, laboratory workers, nurses, and teachers. An attempt is made to present medical bacteriology in such a way that it will be more understandable to those who come in contact with its many ramifications.

A unique feature of the book is the 160 pages devoted to a discussion of diseases from the viewpoint of etiology, epidemiology, type of specimen for examination, laboratory procedures, and methods of reporting. Excellent judgment is shown in the choice of laboratory procedures, which are clear and up-to-date.

Other chapters deal with specific procedures, such as cultivation, isolation, general techniques as used in bacteriology, the use of laboratory animals and culture media, and general information regarding virology and mycology. An excellent chapter on the collection of specimens and the principles involved adds materially to the value of the book for clinicians and laboratory workers.

The appendix is exceptionally well treated, with clear tables regarding diseases, causative agents, specimens for

examination, pertinent animal and serologic tests, stains, reagents, and diagnostic antigens and antisera.

This well organized text, with its abundance of factual information, should be available in every laboratory doing bacteriologic and serologic diagnostic tests. MELVIN E. KOONS

The Pathology of Nutritional Disease—
By Richard H. Follis, Jr., M.D. Springfield, Ill.: Thomas, 1948. 291 pp. Price, \$6.75.

This book fills a real need and both Dr. Follis and the publisher are to be congratulated, the former for getting together in one place the pertinent pathology involved in many nutritional deficiencies, and the latter for doing a good job of printing and reproduction of the pathology plates. The best sections of the book deal with the author's own work on the pathology of scurvy and rickets. The subtitle of the book is "Physiological and morphological changes which result from deficiencies of the essential elements, amino acids, vitamins, and fatty acids." In general, the sections dealing with physiological changes are so brief that one might question whether they should even have been included, but certainly not in the subtitle. The book is well written and reads easily. The author's frequent use of the phrase "of course"—"such changes are, of course, partially explained by the deranged calcium and phosphorous metabolism . . .—arginine is probably one of the precursors of creatine and, of course, acts as a catalyst in the synthesis of urea . . ." tends to over simplify many statements. Everyone in the field of experimental nutrition will enjoy and

thank Dr. Follis for his splendid contribution.
FREDERICK J. STARE

Hearing and Deafness—A Guide for Laymen—*Edited by Hallowell Davis, M.D. New York and Toronto: Murray Hill Books, Inc., 1947. 496 pp. Price, \$5.00.*

According to the Editor, "This book is written for the deaf and the hard of hearing and for their families, their parents, their teachers and their friends. It is written for physicians, for educators, for social workers, and for all who are concerned with the conservation or improvement of remaining hearing; or with the approach to normal living for those who have suffered either complete or partial hearing loss." Dr. Davis and his thirteen contributors have written an admirable book which should be on the shelves of public health workers whose programs include, or should include, programs of hearing conservation.

Certain sections are too difficult for some readers; however, they are clearly posted in advance so they may be omitted if the reader wishes. For the most part the book is easy to understand. It is interesting and scientifically sound.

Public health workers will find the chapter on testing for hearing especially useful. That on the psychology of the hard of hearing and deaf is illuminating. The chapter on hearing aids has many practical tips for the user of aids. The reader cannot fail to be impressed by the many professional skills, including speech reading, auditory training and vocational guidance that must be utilized to meet the needs of patients adequately, and by the large number of hard of hearing and deaf people in the United States.

The public health administrator will be interested in the chapter on the military program of aural rehabilitation. By analogy he can learn of the organization of services required for many civilian needs. Although organizations for

the aurally handicapped are discussed, the administrator will look in vain for a complete discussion of the efforts made in the United States to develop Conservation of Hearing Programs as part of community health programs. An additional chapter summarizing programs such as those stimulated by the Children's Bureau would have made this fine book even better—at least for the health administrator, for whom it was not primarily written.

WILLIAM R. WILLARD

Communicable Disease Control—*By Gaylord W. Anderson, M.D., and Margaret G. Arustein, R.N. (2nd ed.). New York: Macmillan, 1948. 450 pp. Price, \$5.00.*

The seven years that have elapsed since the publication of the first edition of this excellent work on public health have witnessed many important changes in communicable disease control, most of which have been included in this new edition. New antibiotics, sulfonamides, and antigens have come into common use for the prevention and control of many infections, and their application to preventive medicine has been capably described.

As in the previous edition, the first part of the book deals with the control of the communicable diseases in general; the second with the prevention and treatment of particular diseases. A chapter on rheumatic fever has been added. On the whole, an excellent textbook on preventive medicine has been achieved and only a few minor criticisms can be made.

On page xiii the list of tables spread through the text fails to give the page numbers where the tables can be found. Incubation periods mentioned are not all in entire agreement with those usually found in medical texts. For instance, that of mumps is given as 3 weeks instead of the more usually stated 16 to 18 days. In the bibliographies,

although this is a 1948 book, there are very few references to articles appearing in 1947; and for the chapter on poliomyelitis, a subject on which there has been a great deal written in the last two years, there is no 1947 reference and only one for 1946.

This book can be very warmly recommended to doctors and nurses working in the public health field, and pediatricians interested in preventive medicine will also find much of interest and value in a study of this text.

PHILIP M. STIMSON

Public Health Administration in the United States—*By Wilson G. Smillie. (3rd ed.) New York: Macmillan, 1947. 637 pp. Price, \$6.50.*

This third edition, published seven years after the second, is divided into four parts.

The first presents an analytical and historical development of the public health movement. The functions of public health are listed by Smillie as Sanitation, Control of Communicable Diseases, Public Health Education, Individual Health Protection, and the Development of a Nation-Wide Program of Adequate Comprehensive Medical Care.

Part two summarizes the many scientific and administrative developments in the control of communicable diseases: particularly streptococcal infections, as a group of diseases; tuberculosis with case finding rules and mass surveys; malaria and chemotherapy; meningococcus meningitis and sulfonamide prophylaxis. Critical evaluation of community immunization procedure is an important contribution. The numerous charts, maps, diagrams, and an extensive bibliography add to the value of the text.

Part three contains a chapter on each of eleven basic activities of a health department. The child health chapter covers the entire gamut of services from maternal hygiene and the EMIC pro-

gram through school health, with emphasis on dental hygiene.

Part four is the most outstanding of the book. For the student or teacher of public health practice it is a good summary of the federal agencies and the types of administration existing in the states, municipal, and rural areas. It includes a discussion of voluntary agencies and disaster relief. Final chapters span administrative problems from public relations with the medical profession to budgets and personnel training.

An appendix contains personnel qualifications for some of the key positions of the health department.

The text reflects the experiences brought to public health from World War II. It is an excellent text for students of public health, particularly those without experience or a medical background. It is a reference book which each health department should make available to its personnel.

VLADO A. GETTING

A Synopsis of Hygiene—*By G. S. Parkinson, D.P.H., assisted by Kathleen M. Shaw, M.B.E. (9th ed.) London: J. and A. Churchill Ltd., 1947. 791 pp. Price, \$8.25.*

The Jameson and Parkinson textbook on hygiene has been revised faithfully since the first edition appeared in 1920. This ninth edition is the first to indicate the influence on public health practice of the Education Act of 1944, the National Health Service Act and the National Insurance Act of 1946. Further modifications in the text result from changes in British hospitalization policies and from changes in the requirements for the Diploma of Public Health. The reader of this edition is constantly impressed with the impact of social legislation and increasing authority of the Ministry of Health upon British public health.

The material in this book is a veritable treasury of technical information

on public health and preventive medicine., Organization of material differs considerably from that found in American textbooks. The epidemiologist will find no particular order of presentation of disease control; the industrial hygienist will have to browse through at least four of the nine sections; there is little help for those who are interested in the public health laboratory or in nursing. But public health and hospital administrators, engineers, nutritionists, maternal and child hygienists, and those interested in public health law will find this volume constantly useful as a reference guide. CHARLES E. SHEPARD

A Manual of Medical Parasitology, with Techniques for Laboratory Diagnosis and Notes on Related Animal Parasites—By C. Courson Zelif, M.S., Ph.D. State College: Pennsylvania State College, 1947. 159 pp. Price, \$3.75.

This is a paper-bound, lithoprinted volume of typewritten notes, tables, and keys, describing the appearance and morphology of parasites—principally of man—and laboratory methods, direct and indirect, of recognizing various types of parasitic infection. The symptomatology, treatment, and prevention of parasitic disease are scarcely mentioned. A classification of human parasites by phylum, class, order, family, genus, and species is included, and special sections deal with medical protozoölogy, helminthology, arachnology, and entomology. These are illustrated by some 68 figures on 13 plates. None of these are original with the author and many of them are so reduced in size and poorly reproduced as to be worthless; in many instances the captions cannot be read without a reading glass. Numerous tables of differential characteristics and keys for the separation and identification of related forms are presented; the majority of these are reprinted from well known texts on parasitology. The typescript

was poorly proof-read and abounds in errors of punctuation, spelling, grammar, and diction. The compilation of notes on laboratory techniques is useful, as it includes very recent observations and developments in this field, but these are not treated critically. References are given throughout the text, in footnotes and at the end of the volume.

JUSTIN M. ANDREWS

American Medical Research, Past and Present—By Richard H. Shryock, Ph.D., New York: The Commonwealth Fund, 1947. 350 pp. Price, \$2.50.

This monograph, one of the studies prepared under the auspices of the Committee on Medicine and the Changing Order of the New York Academy of Medicine, is a very worthy addition to that series. Dr. Shryock presents an account of the development of American medical research from the middle of the 18th century to the present. Particular emphasis is placed on the developments of the past half century and on their relevance for the present state of medical research.

Beginning with the formative influences that shaped American medical research—British, 1750–1820; French, 1820–1860; German 1860–1895—the author traces the factors that led, around the turn of the century, to the emergence of American medicine on “a level of cultural independence.” The multifarious elements that enter into the activity known as research are dealt with judiciously and in proper perspective. Dr. Shryock examines the rôles of institutions (Johns Hopkins Medical School) and of persons (William H. Welch), and appraises the significance of private support and the rise of the great philanthropic foundations for the maturation and growth of medical research.

Within the brief compass of this volume, the author examines such important questions as the relation of research to teaching, academic salaries,

medical publications, trends in medicine, and the impact of the changing social and economic background on private and public agencies in supporting research. Finally, he points out that mere technical advance is not enough. What is needed in addition is an appreciation of the cultural significance of science itself. This can be obtained by means of historical perspective. Toward this end Dr. Shryock's volume is a solid contribution. GEORGE ROSEN

Health Instruction Yearbook, 1947
—*Edited by Oliver E. Byrd, M.D.*
Stanford, Calif.: Stanford University Press, 1947. 325 pp. Price, \$3.00.

The 1947 edition of the *Health Instruction Yearbook* will take its place as a welcome companion volume to the *Yearbooks* of preceding years. Because of the increasingly rapid flow of experience in medicine, public health, and allied fields, there is great need for a volume such as this which records in a most convenient form summaries of recent health developments.

As in previous editions of the *Yearbook*, the editor has cast his net wide and has secured information on subjects ranging from the vitamin content of mushrooms to the details of the charter of the World Health Organization. Very little of importance on the health scene of 1947 has been omitted. One feels, however, that certain items might have been deleted. For instance, there seems little reason for the entry about a former postmaster general and his high blood pressure. Nevertheless, this item is indicative of the miscellany of health information to be found in the *Yearbook's* pages.

The editorial labor involved in compiling a book of this sort is exemplified by the editor's prefatory statement in which he says that 1,672 articles and news sources were reviewed. Of this number 323 were culled for inclusion in the 1947 edition. Thus, one can be as-

sured that the text touches on practically every aspect of health that excites interest today. Moreover, the editor's introductory comment to each chapter are as interesting and useful as the factual items treated.

The book is highly commended. As a ready reference source, it is admirably compiled and organized. Every public health library should possess this volume for the *Yearbook* is not only a notable undertaking but an unmixed blessing to those who want to keep abreast of progress in the profession.

JOHN LENTZ

Opiate Addiction—*By Alfred R. Lindesmith. Bloomington, Ind.: Principia Press, 1947. 235 pp. Price, \$3.00.*

In this volume, Professor Lindesmith "... aimed to develop ... an interpretation that would ... cover all instances of drug addiction." His understanding of the physiological and emotional mechanisms of drug addiction is meager, his arguments specious and his proposed "reforms" dangerous to the public health. The book and other writings of Professor Lindesmith represent armchair philosophical rumination on material obtained from "sixty to seventy" addicts about fifteen years ago. He declined, as unnecessary, an opportunity to study several hundreds of addicts before writing the book.

The author's thesis is that habitual users of narcotic drugs do not become addicts until after they have experienced withdrawal distress, known its nature, experienced relief of withdrawal symptoms by readministration of the drug, and have learned the name of the drug. This explanation will not satisfy most students of drug addiction. In the first place, it does not explain why the habitual user or "future addict" takes the drug often and regularly enough to become physically dependent on it, nor does it explain animal addiction. In the

second place, Professor Lindesmith does not understand that addiction and read-diction depend upon personality characteristics and emotional needs; he does not recognize the "addiction-prone" individual repeatedly described by Kolb and others. Most readers will be astonished at the naivete with which the author, without knowledge or regard for psychiatric concepts, has the temerity to discuss dynamics of drug addiction.

In spite of known weaknesses of "police" control of narcotic addiction in the United States, which the author proposes to abolish, the fact remains that since the Narcotic Act was passed in 1915 there has been a substantial decline in the number of addicts in this country, although the author leaves one in doubt as to whether he believes a decrease in drug addiction is really desirable.

Professor Lindesmith approves federal hospitals for treatment of drug addiction for those who wish to go voluntarily, but fails to realize, or thinks it immaterial, that only a very few would choose treatment if drugs were freely available on prescription, as he recommends. He believes the common rationalization of addicts, that drugs make them more efficient. The truth is that addicts who have the quantity of drug they desire become inefficient, lazy, somnolent, and careless of person. Professor Lindesmith mentions as an advantage of this free prescription that contraband drug traffic would be wiped out, and the addicts would be able to get their required drugs at a reasonable price, as if that were desirable. Public clinics and free prescription of drugs for addicts have been tried several times with disastrous results; addicts deceive the physicians and get extra drugs which they peddle in contraband channels, or give to their friends, who then become eligible for dispensation of drugs and a

vicious spread of addiction is thus established.

Proposal for unrestricted prescription of narcotics for addicts is naïve in the extreme and dangerous to the public health of the nation. Fortunately, sounder judgment than the author's will prevail and there is no likelihood of the "reforms" which he proposes being carried out.

VICTOR H. VOGEL

Symposium on Medicolegal Problems. Under the Co-sponsorship of the Institute of Medicine of Chicago and the Chicago Bar Association—*Edited by Samuel A. Levinson, M.D., Ph.D. Philadelphia: Lippincott, 1948. 255 pp. Price, \$5.00.*

On those rare occasions when doctors and lawyers get together to discuss mutual problems both groups invariably learn something. At six notable meetings of this sort the members of these two professions in Chicago gathered to listen to papers and to ask questions about: (1) the medical witness; (2) artificial human insemination; (3) the practice of pathology; (4) operations for sterility; (5) trauma and cancer; and (6) blood tests for paternity and chemical tests for intoxication. These vexing problems were clarified and explained, if not exactly solved, by speakers representing the medical and legal points of view, supplemented by discussion from the floor, which is fully reported and sometimes is more brilliant than the original paper. Although based mainly on Illinois experience, the material is of general interest and value, and might well set a pattern for similar assemblies in other states or in the larger cities. This well printed book will appeal to those who are concerned with the six special medicolegal problems which are so ably discussed in it.

JAMES A. TOBEY

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

In Battle Array—What the National Cancer Institute will do with the fourteen millions entrusted to it should prove an effective antidote against despair. It's assuring just to read of the magnitude and the scope of the work, being done without fanfare, fireworks, or benefit of radio comedians.

ANON. The Program of the National Cancer Institute. *Pub. Health Rep.* 63, 16:501 (Apr. 16), 1948.

From the Experts—Though a half million syphilitics have been treated with penicillin, and though that drug is now the principal agent employed, treatment is not yet entirely standardized. This report is the last word in that direction.

ANON. The Status of Penicillin in the Treatment of Syphilis. *J.A.M.A.* 136, 13:873 (Mar. 27), 1948.

"Theirs Not to Reason Why"—Having proved himself to be an effective delinquent case chaser-upper the put-upon Western Union messenger was sent out to bring in reported venereal disease contacts. Of the 1,500 he called upon, 47 per cent reported within 3 days, a better response than health board visitors procured.

BAUER, T. J., *et al.* The Telegram as a Case-Finding Technic in Venereal Disease Control. *Ven. Dis. Inform.* 29, 2:42 (Feb.), 1948.

Human Souls, Not Cases—This is an effective plea for more and better social work in connection with the detection and care of the quarter million tuberculosis patients we have on our national hands.

BLOOM, S. Some Economic and Emotional Problems of the Tuberculosis Patient and His

Family. *Pub. Health Rep.* 63, 14:448 (Apr. 2), 1948.

One in Six Gets It—It's time we did something more about trichinosis, this distinguished committee says. It recommends excluding from New York pork from hogs fed uncooked garbage, prohibiting shipment of uncooked garbage from town, and its feeding in-town, among other measures.

CORWIN, E. H. L., and PRICE, L. Control of Trichinosis (Committee Report) *Pub. Health Rep.* 63, 15:478 (Apr. 9), 1948.

Incidental Intelligence—Reported cases of polio were fewer in 1947 than any year since 1942. Epidemics occurred in only small areas. England and some of the continental countries were hard hit.

DAUER, C. C. Incidence of Poliomyelitis in 1947, (and) BRADLEY, W. H., and GALE, A. H. Poliomyelitis in England and Wales in 1947. *Pub. Health Rep.* 63, 13:393 (Mar. 26), 1948.

Science Marches On—Don't let the word "therapy" in the title persuade you that this paper is for practising physicians only. It is for every professional worker who wants to know what's back of the rule-of-thumb nutritional precepts he preaches to others, or neglects to apply to himself. Not to be missed!

ELVEHJEM, C. A. Recent Progress in Nutrition and Its Relation to Drug Therapy. *J.A.M.A.* 136, 14:915 (Apr. 3), 1948.

Canners, Take a Bow!—From a year-long nation-wide survey of canned, frozen, and fresh fruit and vegetables comes the conclusion that canned foods cost least and offered the best nutri-

tional values from an economic standpoint.

KREHL, W. A., and COWGILL, G. R. Comparative Cost and Availability of Canned, Glassed, Frozen, and Fresh Fruits and Vegetables. *J. Am. Dietet. A.* 24, 4:304 (Apr.), 1948.

They're Still at Large—Note for your book: penicillin applied locally cleared up diphtheria carriers.

LEVY, A. J. Local Treatment of Carriers of Virulent Diphtheria with Penicillin. *J.A.M.A.* 136, 13:855 (Mar. 27), 1948.

Facts About Food—Promised as the first of a series of papers on nutrition (to be published later in book form), this one is full of facts about cereals, legumes, vegetables, and fruit. I can't remember ever reading an article with more facts heaped up, pressed down, and pounded in, than this one.

MAYNARD, L. A., and NELSON, W. L. Foods of Plant Origin. *J.A.M.A.* 136, 16:1043 (Apr. 17), 1948.

As Our Population Ages—First of a series of statistical papers on heart disease morbidity and mortality, this one presents two graphs you should find useful, the percentage of population in age groups and percentage of deaths in these groups. A more dramatic presentation of the fact that our saving of lives has been in childhood and early adult ages would be difficult to conceive.

MORIYAMA, I. M., and GOVER, M. Statistical Studies of Heart Disease. *Pub. Health Rep.* 63, 17:537 (Apr. 23), 1948.

Anent Healing Thyself—How are you? Do you bite your nails, drink too much, take barbiturates? Does your anger or fit of tension persist beyond natural limits? Do you enjoy ill-health? You may still not be beyond gaining a better insight into your own condition by reading this dissertation on psychosomatic medicine, which, the writer points

out, is akin to preventive medicine in many ways.

RUESCH, J., and BOWMAN, K. M. Personality and Chronic Illness. *J.A.M.A.* 136, 13:851 (Mar. 27), 1948.

1948 Complications—Ping-pong syphilis is a new descriptive for your vocabulary. The infection is batted back and forth from the infectious partner to the one who has just completed treatment. Under penicillin therapy the situation is not rare. Ways to stop it are discussed.

SCHAMBERG, I. L., and STEIGER, H. P. Syphilitic Relapse vs. Reinfection. *Ven. Dis. Inform.* 29, 4:92 (Apr.), 1948.

State Paper—Preventive geriatrics, mental health, and research seem to be uppermost in the mind of the new Surgeon General as he takes command of the U.S.P.H.S. You'll want not to miss this address.

SCHELLE, L. A. The Road Ahead in Public Health. *Pub. Health Rep.* 63, 15:472 (Apr. 9), 1948.

You'll Be Surprised—As part of their course of training these students were required to go out and start a group along the road to better health. Some of the unusual enterprises the youngsters thought up are briefly described.

STEINHAUS, A. H. Adventures in Health Education. *J. School Health*, 18, 4:103 (Apr.), 1948.

DeLuxe Model—This is about an agreement worked out between the executive officers of the Rochester (Minn.) Public Schools and the Public Health Department, to provide complete school health services by a staff of 25 qualified physicians, nurses, and educators—for 5,000 children.

THOMAS, M. J. Unifying Health Services Through Public Education. *Pub. Health Nurs.* 40, 4:168 (Apr.), 1948.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- ASEPTIC TREATMENT OF WOUNDS.** Carl W. Walter, A.B., M.D. New York: Macmillan, 1948. 372 pp. Price, \$9.00.
- BIOLOGY AND HUMAN AFFAIRS** (new ed.). John W. Ritchie. New York: World Book Company, 1948. 818 pp. Price, \$3.40.

- WEST VIRGINIA MERIT SYSTEM COUNCIL. 5th Report. January 1, 1946 to June 30, 1947. Charleston, W. Va. Office of the Supervisor. 26 pp.

cations are accepted up to August 1 each year for consideration by the Governing Council at the fall meeting. It is important to make clear that members themselves should take the initiative in submitting such applications. Neither the Sections nor the A.P.H.A. administrative staff are authorized to solicit applications. This means that, although nearly 3,000 persons have been duly recognized with this grade of affiliation since 1922, there are other persons well qualified who have never initiated the process of applying for Fellowship. It should be clear that members should not await action by others if they wish to attain Fellowship. It is necessary and proper for them to take the first step.

An application for Fellowship requires sponsorship by two Fellows of the Section with which the applicant desires to be affiliated. These personal signatures are to be obtained by the applicant before submitting the completed application. The A.P.H.A. office will assist, on request, in determining the Section with which prospective sponsors are affiliated. Applications from persons not wishing to be identified with a particular Section and requesting unaffiliated Fellowship may be sponsored by any two Fellows of the Association.

When properly sponsored and otherwise completed, the application is sent to the A.P.H.A. office, after which the list of persons applying is published in the *American Journal of Public Health*, usually in the September issue, but in any case not less than 15 days before the date for the Annual Meeting. An established routine is followed for review by the Section Councils (unaffiliated applications are reviewed by the Executive Board) and by the Commit-

tee on Eligibility. This Standing Committee of the Association is made up of one Fellow from each of the 12 Sections, plus a Chairman elected by the Executive Board. This group is under instructions from the Governing Council to examine each application in accordance with the provisions of the clause of the By-laws chosen by the applicant, and to apply the criteria with precision in each case. Final election is by the Governing Council at the second meeting at each annual session.

The privileges of Fellowship include eligibility to serve as an officer of the Association or one of the Sections, Chairman of an Association or Section Committee (over one hundred in number), a member of one of the four Standing Committees, a member of the Governing Council or Executive Board, and the right to vote at the Annual Meeting for the elective members of the Governing Council and on amendments to the Constitution. Some Civil Service and merit system records depend upon Fellowship in the American Public Health Association as an achievement deserving recognition in applicants.

The dues of Fellows are \$12.00 annually, and include a subscription to the *American Journal of Public Health* and other services to which members are eligible. Life Membership is available at \$200, covering all future annual dues.

Applications for Fellowship to be considered at the 76th Annual Meeting in Boston, Mass., November 9-12, 1948, should be filed with the Association as soon as they are completed, and in any case not later than August 1. For further information, address the Membership Department, American Public Health Association.

THE 76TH ANNUAL MEETING

Boston, Mass., November 8-12, 1948

Hotel Reservation Form

The hotels listed below have rooms available for Association delegates at the rates indicated. Please note that NO RESERVATIONS WILL BE ACCEPTED DIRECTLY BY HOTELS. Make your reservation through:

The Convention Bureau, Boston Chamber of Commerce, 80 Federal Street, Boston 10, Mass.

THE HOTEL IS NOTIFIED OF LATE ARRIVALS

APPRECIATION OF DR. CARL E. BUCK

BY THE C.A.P.

At its meeting in New York in March the Executive Committee of the Committee on Administrative Practice adopted the following resolution with respect to Dr. Carl E. Buck who resigned his position as Field Director of the Association in February to become Resident Lecturer in Public Health at the University of Michigan School of Public Health:

BE IT RESOLVED that we, the members of the Executive Committee, for ourselves and for all the members of the Committee on Administrative Practice, express herewith our deep regret that Dr. Carl E. Buck, Field Director, has found it necessary to resign from this important position after seventeen years of continuous service.

Since his appointment in 1931 he has completed surveys of 17 states, the Territory of Alaska, and the Province of Manitoba. His studies have included 36 local communities—cities and counties—and follow-up consultant and advisory visits to the number of 64 in states where studies had been made.

This formidable list of detailed inquiry and recommendation for the administration of state and local health departments does not include a multitude of services to states, cities, and counties in connection with the Evaluation Project or his participation at conferences, institutes, and national, state, and local public health meetings.

His loyalty to the professional objectives and standards of the American Public Health Association, his critical and constructive analyses of official and voluntary health services, and his persuasive and courageous expressions of sound opinion for the betterment of these, often in the face of political, popular, or press criticism, have marked his labors with high quality and consistency.

Dr. Buck's personal and professional contributions to the work he undertook have left a permanent mark upon the purpose and pattern of public health service in the United States and Canada.

The committee wishes him many years of further productive contribution to the teaching of the principles of public health administration in the friendly and coöperative atmosphere of an academic environment.

COMMITTEE ON ADMINISTRATIVE PRACTICES OF THE INDUSTRIAL HYGIENE SECTION

Omitted inadvertently from the Committee List published in the *Year Book* was the following committee of the Industrial Hygiene Section:

COMMITTEE ON ADMINISTRATIVE PRACTICES

J. G. Townsend, M.D., *Chairman*, Industrial Hygiene Division, U. S. Public Health Service, Washington 25, D. C.
 W. E. Frederick, Ph.D.
 J. M. MacDonald, M.D.
 V. A. Nasatir, M.D.
 M. F. Trice, B.S.
 Miss J. Y. Ziano

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

J. R. Brandon, M.D., City Health Dept., High Point, N. C., City Health Officer
 Arthur F. Chaisson, M.D., C.M., Provincial Dept. of Health, Fredericton, N. B., Canada, District Medical Health Officer
 Gerald R. Clark, M.D., 411 Capitol Bldg.,

Phoenix, Ariz., Senior Asst. Surgeon, U.S.P.H.S., Director of Tuberculosis Control, State Health Dept.
 Catherine E. Coleman, M.D., Clay County Health Dept., West Point, Miss., Health Officer
 William E. Gregson, M.D., M.P.H., Sick Mari-

ners' Clinic, Immigration Bldg., Vancouver B. C., Canada. Quarantine Officer in Charge

Vane M. Hoge, M.D., U. S. Public Health Service, Washington, D. C., Medical Director and Chief, Division of Hospital Facilities

Philip A. Klieger, M.D., Cass Lake Indian Hospital, Cass Lake, Minn., Senior Physician, U. S. Indian Service

Adolph G. Liedloff, M.D., 222 South Front St., Mankato, Minn., Acting Director, District No. 2, State Dept. of Health

E. E. McClellan, M.D., Kaparoulis Bldg., Williamson, W. Va., Mingo County Health Officer

Ruth McDougall, M.D., D.P.H., Red River Health Unit, Ste. Anne des Chenes, Man., Canada, Medical Director

Alejandro Guevara-Rojas, M.D., M.P.H., Martires de Tacubaya 70, Mexico, D. F., Mexico, Director, Unidad de Salubridad y Estacion de Adiestramiento de Xochimilco

John W. Spies, M.D., M.P.H., State Board of Health, Marshallton, Dela., Director, Divisions of Cancer Control and Communicable Diseases, State Board of Health

Leroy K. Young, M.D., U. S. Public Health Service, Manila, Philippines, Consultant on Tuberculosis to Philippine Public Health Rehabilitation Program and Chief, Tuberculosis Control Division, U.S.P.H.S.

Laboratory Section

Rena L. Dodd, 1026 New Scotland Road, Slingerlands, N. Y., Bacteriologist, State Dept. of Health

E. H. Garrard, M.S., Dept. of Bact., Ontario Agricultural College, Guelph, Ont., Canada, Professor and Head, Dept. of Bacteriology

Roderick D. Hamblin, 3086 Stoddard Ave., San Bernardino, Calif., Laboratory Director, San Bernardino County Public Health Laboratory

Dorothy Lewis, Richards Chemical Works, 190 Warren St., Jersey City 2, N. J., Research Bacteriologist and Laboratory Supervisor

Irving J. Lipovsky, M.S., Biology Dept., Univ. of Massachusetts, Fort Devens, Mass., Asso. Professor of Bacteriology

Denys R. Lock, M.A., 1709-21st St., Everett, Wash., Director of Laboratory, Providence Hospital

Frank R. Martuccio, 1422½ Barry Ave., West Los Angeles, Calif., Bacteriologist, U. S. Veterans' Center

Celia Rubin, 2839 India St., San Diego, Calif., Senior Laboratory Technician, City Public Health Laboratory

Helen R. Seraichekas, 19 Barrett St., Cranston,

R. I., Medical Technician, U. S. Veterans' Administration

Kenneth E. Shull, 762 Lancaster Ave., Bryn Mawr, Pa., Chief Chemist and Superintendent of Purification, Philadelphia Suburban Water Co.

Kenneth W. Stewart, 1217 Harrison, Kansas City, Mo., Production and Quality Control, Franklin Ice Cream Co.

Vital Statistics Section

Vira Anderson, R.N., Salem Memorial Hospital, Salem, Ore., Medical Record Librarian

Stephen S. Henkin, 555 Prospect Place, Brooklyn 16, N. Y., Chief Record Librarian, Jewish Hospital of Brooklyn

Judith Killeen, 6300 Beacon Ave., Seattle 8, Wash., Advisory Field Clerk, State Dept. of Health

Virginia M. Riley, Barre City Hospital, Barre, Vt., Chief Record Librarian

Henry S. Robinson, 23 Grove St., New York 14, N. Y., Field Statistician, American Cancer Society

Martha C. Wood, 237 Pontotoc, Houston, Miss., Business Manager and Medical Record Librarian, Houston Hospital

Engineering Section

Irwin G. Bircher, D.V.M., 50 University Ave., Rochester 5, N. Y., County Veterinarian

Harlan G. Formo, M.P.H., 115 Court House, Duluth, Minn., Public Health Engineer, District IV, State Health Dept.

Alfred A. Gannon, 16205 Tracey, Detroit 27, Mich., Sanitarian, Wayne County Health Dept.

Pharm. Ralph T. Goerner, Jr., (HC) USN, U. S. Naval Station, Treasure Island, San Francisco, Calif., Sanitarian

Eric J. Hanneemann, 806 Highland Ave., Austin, Tex., Graduate Work in Sanitary Engineering, Univ. of Texas

Bernard L. Jacobson, Box 2892, University, Ala., Student, Univ. of Alabama

C. C. Potter, 3520-54th, Des Moines 10, Iowa, Asst. Sanitary Engineer, State Dept. of Health

Thomas J. Rinaldo, 465 Concord St., Framingham, Mass., Asst. Sanitary Engineer, Water Division, Metropolitan District Commission

Major Clyde M. Turner, MSC, 9829th TSU, Engineer School, Ft. Belvoir, Va., Sanitary Engineer

Industrial Hygiene Section

George G. Richards, 1940 South 16th East, Salt Lake City 5, Utah, Industrial Hygiene Technician, State Health Dept.

Food and Nutrition Section

- Marian L. Arnold, 172 Westminster St., Hamden 14, Conn., Nutrition Director, Connecticut Dairy and Food Council
- Slava Malec, 217 E. Broad St., Bethlehem, Pa., Staff Nutritionist, State Dept. of Health
- Margaret A. Ohlson, Ph.D., Michigan State College, East Lansing, Mich., Head, Foods and Nutrition Dept.

Maternal and Child Health Section

- Catherine D. Carlson, M.D., International House, Berkeley 4, Calif., Student, School of Public Health, Univ. of California
- Ernest W. Hancock, M.D., 1103 State House, Lincoln, Neb., Chief, Division of Services for Crippled Children, Dept. of Assistance and Child Welfare
- Pedro Magana-Erosa, M.D., 10/a. de Puebla 204, Depto. 6, Mexico, D. F., Mexico, Pediatrician, Unidad Sanitaria y Estacion de Adiestramiento de Xochimilco
- Henrietta L. Marquis, M.D., Medical Arts Bldg., Charleston, W. Va., Pediatric Consultant, State Health Dept.
- Ursula G. Sanders, M.D., 17 Capitol St., Concord, N. H., Asst. Director, Maternal and Child Health Division, State Dept. of Health
- Jessie J. Turnbull, Sc.D., Elizabeth Steel Magee Hospital, Pittsburgh 13, Pa., Supt.

Public Health Education Section

- Samuel J. Barham, 601 Topeka Blvd., Topeka, Kans., Exec. Director, Kansas Hospital Service
- Francis G. Bean, M.D., 223 Washington Ave., Bennington, Vt., Administrator, Putnam Memorial Hospital
- Mary I. Cawley, 364 Edison St., Staten Island 6, N. Y., Public Health Analyst, Venereal Disease Research Laboratory, U.S.P.H.S.
- Louie H. Crowl, D.D.S., 3201 Cutter Way, Sacramento 17, Calif., Director of Health Education, McClellan Air Force Base
- Ruth L. Flater, 526 Goodwyn Institute, Memphis, Tenn., Sec., Health Section, Community Council of Memphis-Shelby County
- Arden E. Hardgrove, 231 West Oak St., Louisville 3, Ky., Administrator, Norton Memorial Infirmary
- Ruskin King, M.D., 10 West Taylor St., Savannah, Ga., Private Pediatrician
- Fraser D. Mooney, M.D., C.M., 100 High St., Buffalo 3, N. Y., Supt., Buffalo General Hospital
- Mary H. Parks, M.P.H., 18 Dove St., Albany, N. Y., Asso. Public Health Educator, State Dept. of Health

Willard C. Rappleye, M.D., Sc.D., 630 West 168th St., New York, N. Y., Dean, Faculty of Medicine, Columbia Univ.

Lauritz S. Ylvisaker, M.D., Fidelity Mutual Life Insurance Co., 25th and Parkway, Philadelphia, Pa., Vice-President and Medical Director

Lawrence Zuccolo, 723-17th St., Union City, N. J., Student, New York Univ.

Public Health Nursing Section

- Maude C. Bailey, M.A., 4217 Blossom St., Columbia, S. C., Hospital Consultant, Maternal and Child Health Division, State Board of Health
- Margaret G. Bennett, c/o North American Embassy, Montevideo, Uruguay, S. A., Consultant Public Health Nurse, Institute of Inter-American Affairs
- Anna K. Bergstrom, R.N., 307 Court House, Springfield, Mo., Public Health Nurse, State Crippled Children's Service
- Judith S. Cantor, 500 Riverside Drive, New York, N. Y., Student, Teachers College, Columbia Univ.
- Florence M. Clark, R.N., 17 Capitol, Concord, N. H., Director, Public Health Nursing Division, State Dept. of Health
- Elizabeth Dills, R.N., B.S., George A. Hormel & Co., Austin, Minn., Nurse Consultant and Visiting Nurse
- Amelia M. Engel, 2300 Bronx Park East, Bronx 67, N. Y., District Supervising Nurse, City Dept. of Health
- Hylde A. Harp, R.N., M.P.H., 2825 N. 58th St., Milwaukee, Wis., Supervisor of School Hygiene, City Health Dept.
- Lucile M. Johnson, R.N., B.S., 805 Sixth St., Eureka, Calif., Supervising Public Health Nurse, Humboldt County Dept. of Health
- Genevieve S. Jones, 2405 First St., N. W., Washington, D. C., Senior Asst. Nurse Officer and Tuberculosis Nursing Consultant, U. S. P.H.S.
- Marjorie A. McIntosh, Ottawa Civic Hospital, Range Rd., Ottawa, Ont., Canada, Instructor of Nurses and Asst. Supervisor, Communicable Disease Unit
- Birdie M. McKee, R.N., B.S., Red Cross Nursing Service, 14 Park Ave., Caldwell, N. J., Supervising Nurse
- Eleanor J. Pingrey, 2019 E. 3rd. Ave., Durango, Colo., Student, Univ. of Colorado
- Jeanne Richie, R.N., B.S., R.F.D., Rialto, Calif., Public Health Nurse, Imperial County Health Dept.

NEWS FROM THE FIELD

REGIONAL CONFERENCE ON LOCAL HEALTH UNITS

The first in a series of regional conferences to get home town action on the problem of getting every person in every county under the umbrella of local health protective services was held in Mitchell, Ind., on April 21 and 22. Under the sponsorship of the National Health Council, and planned with the co-operation of the health departments of the five states of Indiana, Kentucky, Michigan, Ohio, and Wisconsin, this conference brought together representatives of a variety of voluntary health and citizen agencies.

The Indiana State Health Department was host to the conference and made arrangements for the details of recording, publicity, stenographic, and other services. It also had the largest delegation.

Except for several resource persons the conference group was selected by the respective state health officers to bring together those interests that could develop most effectively favorable opinion for extending local public health services in their states. The keynote of the conference was accented by Bailey B. Burritt, Executive Director of the National Health Council, in his opening address with a quotation from Woodrow Wilson to the effect that, "The highest and best form of efficiency is the spontaneous coöperation of free people."

The plan of the conference was for a general session the first morning to explore the problem areas to which working committees should devote the afternoon session. The problem areas were resolved into three major groupings, each of which was assigned to a working committee. These committees, each with a discussion leader and a recorder, grappled with their problem during an after-

noon session. Their reports were then presented to the entire conference at an evening session.

The three main problems were defined as (a) securing public demand and support, (b) organization of a plan for each community including a consideration of the legislative and political factors affecting the development of such a plan, (c) accomplishing the plan through provision of adequate funds, a strong state health department, and qualified personnel. The discussions were active, with everyone participating and with colorful illustrations of specific conditions or achievements in the various states. There was universal agreement that local upsurge must be stimulated; that lasting results cannot be achieved by superimposing a state program upon local lack of knowledge and interest. The state's role, both of official and voluntary agencies, is that of stimulation, information, consultation, and assistance. The importance of local assistance in recruitment of personnel was also emphasized as was the necessity for training facilities. Inadequate salaries and an anomalous situation with respect to prestige, particularly as it affects the medical profession in public health, are the chief stumbling blocks to recruitment of personnel in adequate numbers.

The second morning discussions were carried on by the separate state groups. Here the plan was to apply the general findings of the previous day to the particular problems of the respective states. On this day the afternoon was devoted to the state group reports and general discussion of them and to a summing up.

The various state situations were reviewed. Michigan, for example, has nearly 100 per cent coverage but is currently struggling with the problem of personnel and with political currents that

are detrimental to effective completion of coverage. Kentucky, because of the constitutional limitations on salaries of public workers, is under the necessity of holding back demands for additional county units because of failure to secure personnel.

The Wisconsin Legislature has just passed a permissive health unit law and many citizen agencies throughout the state are demanding local action. There is hope that many areas may be organized in the near future. A meeting of 25 representative citizens was held on May 12 to develop a strategy for getting widespread public understanding of and demand for the services of local health departments throughout the state.

Ohio is handicapped by its public health law dividing the state into 203 health districts, a separate one for each city of 5,000 or more, and one for each county outside these cities. Since the law provides for consolidation of districts, however, the state health department has developed a plan for 37 county, city-county, and multi-county health departments to replace its 203 health districts. Some score of voluntary and citizen agencies in the state plan a survey of the various state public health laws as a basis for proposing amendments to the Ohio law.

Indiana's recent legislature passed a permissive health unit act and there is hope that the 1949 legislature will provide state aid to local health departments. One bi-county department has already been organized and sufficient interest has been created in enough areas so that if they become organized half of the state's population will be served instead of less than one-quarter now served.

In summing up the two day discussions, Mr. Burrill used Haven Emerson's Catechism on "What are the Seven Steps to the Temple of Health," which was used as display at the Princeton Conference on Local Health Units in

September, 1947. These seven steps are:

1. A plan by the state health department
2. The organization of a state-wide citizen committee of voluntary and citizen agencies and approved by the governor
3. Completing legislative authority
4. Legal authorization for personnel and salaries
5. Agreement upon tax sources of support—local, state, and federal, for the local health department
6. Recruitment and training of personnel
7. Local community health council follow through to secure results and tax support

About 50 persons attended the conference. Chairmen and reporters of problem and state committees were drawn from the conference membership. Delegates represented parent-teacher associations, the Farm Bureau, CIO, state medical societies, Federation of Women's Club, American Association of University Women, state branches of such national agencies as the National Tuberculosis Association, National Society for Crippled Children, National Foundation for Infantile Paralysis, American Red Cross, as well as representatives of official health agencies. State health commissioners of three of the five participating states attended the conference.

The National Health Council staff is now analyzing the results of the conference with a view to determining whether it represents a pattern for similar conferences in other regions of the country.

AWWA OFFICERS

The following officers of the American Water Works Association were elected recently to take office on May 7, 1948:

- President*—Linn H. Enslow, Editor, Water and Sewage Works
Vice President—A. P. Black, Professor of Chemistry, University of Florida
Treasurer—William W. Brush, Editor, Water Works Engineering

Harry E. Jordan is the permanent secretary of the Association, which has headquarters at 500 Fifth Avenue, New York.

AUSTRALIA'S MEDICAL CARE PROGRAM INCLUDES PHARMACEUTICALS

According to a federal Act, passed in 1947, pharmaceutical benefits now are included in the Australian government's health and social services program. Compiling and reviewing at regular intervals a formulary defining the scope of the benefits is in the hands of a permanent committee of seven members, including three medical practitioners and pharmacologists and pharmacists.

A prescription, in authorized form consisting of items included in the formulary, and signed by a physician, will be presentable without charge to the patient to any chemist or dispensary approved under the Act.

In reporting on this development, the Australian Information Service says, "It is hoped that the public will receive a service not only as good as present practice, but actually better, because of the elimination of drugs long superseded."

DR. PARRAN TO CHILDREN'S FUND

Thomas Parran, M.D., who retired as Surgeon General of the U. S. Public Health Service on April 6, leads a temporary mission to the Far East of the United Nations International Children's Emergency Fund. He is making a study preparatory to the extension of special forms of Children's Fund aid to mothers and children. Dr. Parran's mission is in line with the Fund's Executive Board recent directive that future allocations give special consideration to the needs of children in countries outside Europe. Five and a half million dollars has already been allocated for a child aid program in China, and a million and a half for other Far Eastern Countries.

Dr. Parran's tour of duty, which began late in April and will take about two months, will cover the Philippines, China, Hong Kong, French Indo-China, Malaya, Singapore, Indonesia, Thailand, Burma, Ceylon, India, and Pakistan.

PROFESSOR STARIN RETIRES

William A. Starin, Ph.D., Chairman of the Department of Bacteriology, Ohio State University, was honored at a dinner in Columbus on May 8. He will retire from active service at the end of the academic year, after 38 years of teaching at the university. He is known particularly for his work on filtrable viruses, pathogenic fungi, immunology, and pathogenic bacteriology. He has been a member of the American Public Health Association since 1933 and a Fellow since 1943.

The William A. Starin Lectureship has been established at the university by Professor Starin's friends and former students. Those wishing to share in this permanent tribute may send contributions to Dr. Margaret D. Heise, Department of Bacteriology, Ohio State University, Columbus, Ohio.

NEW BI-COUNTY HEALTH DEPARTMENT IN ILLINOIS

Fred O. Tonney, M.D., is the Health Officer of the recently organized joint health department of Effingham and Shelby counties in Illinois. This department was established as a result of a referendum in 1946. The combined population of the two counties in 1946 was nearly 50,000.

ARMY MEDICAL DEPARTMENT EXPANDS TRAINING PROGRAM

The United States Army Medical Department announces an expansion of its educational and training program, the primary goal of which is an unequalled high standard of medical care for the U. S. Army. Public health training is part of this program with courses in public health, sanitary engineering, hospital administration, and related fields. Medical officers who desire to be certified by American specialty boards can participate in officially recognized programs leading to examination for specialist certification, including the In-

terim Specialty Board in Preventive Medicine recently announced for the medical officers of the services.

All six Corps of the Army Medical Department—Medical, Dental, Nurse, Veterinary, Medical Service and Women's Medical Specialist Corps—and both enlisted men and women and commissioned officers, are represented in these training courses. The Army Medical Department arranges for personnel to take the courses and pays the tuition when required. Full pay and allowance is offered for the period of study at civilian and Army institutions.

PEDIATRICS, A NEW JOURNAL

In January, 1948, *Pediatrics*, the Journal of the American Academy of Pediatrics, began publication. It is "the medium of expression of the Academy to the medical profession and the public," "brings to its readers a comprehensive survey of the pediatrics field," and "publishes original articles on scientific and clinical investigations in the field of pediatrics."

Hugh McCulloch, M.D., is the Editor-in-Chief. Contributing editors are Leona Baumgartner, M.D., of New York, John P. Hubbard, M.D., Director of the Academy's study of child health services, and Dr. Felix Hurtado of Havana.

Annual subscription to this new monthly journal is \$10.00. Manuscripts, books for review, and correspondence concerning editorial matters should be sent to the Editor-in-Chief, 325 North Euclid Ave., St. Louis 8, Mo.; correspondence concerning subscriptions, advertising, and business matters to Charles C. Thomas, Publisher, 301-327 East Lawrence Ave., Springfield, Ill.

CECIL K. CALVERT, 1886-1948

On April 19, 1948, Cecil K. Calvert died at the age of 61. For forty years he served in various capacities in water purification work in Indianapolis, Ind.

In 1908, Mr. Calvert joined the staff of the Indianapolis Water Company becoming Superintendent of Purification in 1936, which position he held at the time of his death. Among his more prominent accomplishments in the field of sanitary engineering was his work with the American Water Works Association, in which he was Chairman of the Water Purification Division and of the Committee on Control of Chlorination. He joined the American Public Health Association in 1927 and became a Fellow in 1946.

LONG ISLAND COLLEGE CONCLUDES POST-GRADUATE COURSE IN INDUSTRIAL MEDICINE

The Fifth Postgraduate Course in Industrial Medicine offered by the Department of Preventive Medicine and Community Health, Long Island College of Medicine, Brooklyn, N. Y., was concluded April 16 after running for two weeks.

Thomas D. Dublin, M.D., Professor and in charge of the course reports that the total enrollment of full- and part-time students was 75, the second largest of the postgraduate courses so far offered. Thirty-one of the matriculants were physicians, 26 nurses, and 18 members of other professions. Students from Belgium, China, and Egypt were included, as were representatives of 26 different organizations in 6 different states. The lectures given for the students are expected to be published in a volume of proceedings.

KANSAS PUBLIC HEALTH ASSOCIATION MEETS

The Kansas Public Health Association held its Sixth Annual Meeting in Topeka on April 16 and 17. At the meeting a feature was a dinner honoring Charles H. Lerrigo, M.D., for forty-seven years of public health service in the state.

The officers who will serve the Kansas

society during the forthcoming year are:

President—M. Leon Bauman, M.D., Parsons

President-elect—James M. Mott, M.D., Lawrence

Secretary-Treasurer—Evelyn Ford, Topeka

The 1949 Annual Meeting of the K.P.H.A. will be held in Pittsburg April 25 to 27.

MICHIGAN PUBLIC HEALTH ASSOCIATION

At its recent annual meeting the following officers of the Michigan Public Health Association were elected:

President—Mildred Cardwell, R.N., Ingham County Health Department

President-Elect—E. Frank Meyer, D.V.M., Grand Rapids

Vice-President—Joseph G. Molner, M.D., Deputy Commissioner and Medical Director, Detroit Department of Health

Secretary-Treasurer—Marjorie Delavan, Director, Bureau of Education, State Department of Health

Representative on Governing Council, A.P.H.A.—Kenneth R. Gibson, D.D.S., Dental Director, Children's Fund of Michigan

ILLINOIS PUBLIC HEALTH ASSOCIATION ANNUAL MEETING

The Illinois Public Health Association held its 8th Annual Meeting in Chicago on April 15 and 16. The attendance was well over 500. New officers were elected as follows:

President—Maude B. Carson, R.N., Springfield

President-Elect—Baxter K. Richardson, Springfield

Secretary-Treasurer—Harold M. Cavins, Ed.D., Charleston

WHO CHARTER RATIFIED

The final meeting in Geneva of the Interim Commission of the WHO on February 7 was climaxed by an announcement that 29 United Nations, 3 more than necessary, had ratified the charter of the WHO. By April 7, 26 of the ratifications had been deposited with the United Nations, thus bringing the WHO officially into being. In addition, 8 nations not members of the

United Nations have ratified the constitution. This announcement was made by its Chairman, Dr. Andrija Stampar of Yugoslavia, who announced that the first session of the World Health Assembly will open in Geneva probably on June 24, 1948.

The United States is not among the member nations that have ratified the charter, the House Rules Committee having tabled the resolution indefinitely on March 12.

The budget of \$6,000,000 adopted by the Interim Commission provides for fellowships, teaching equipment, and medical supplies to meet post-war health problems, world-wide campaigns against malaria, tuberculosis, and venereal diseases, and a top-priority program for mother and child welfare.

LATIN AMERICAN NUTRITION CONFERENCE

In an effort to encourage all Latin American countries to provide their peoples with a healthy diet, the Food and Agriculture Organization of the United Nations will hold a regional meeting of leading nutrition workers at Montevideo, Uruguay, starting July 28. Delegates have been invited from 18 Latin American countries and from France, the Netherlands, the United Kingdom, and the United States. The Argentine Republic, which is not a member of FAO, and interested international organizations have been asked to send observers.

The delegates will determine the gaps in existing knowledge about dietary habits, the state of nutrition, and the prevalence of deficiency diseases. They will plan measures to fill these gaps and attempt to develop and dovetail their national plans into a concerted attack to improve the nutrition of the people.

Serious malnutrition due to deficiency of protein, certain minerals, and vitamins, exists in many Latin American countries. Despite the fact that total

food production has increased in parts of Latin America, a large proportion of the population still exists on inferior and ill-balanced diets.

Recommended by the FAO Geneva Conference last summer, the 10 day meeting is the second of a world series planned by FAO on nutritional problems. The first, held in the Philippines in February, 1948, was concerned mainly with ways and means of improving rice diets in South East Asia.

PROGRESS IN STREAM POLLUTION CONTROL

About the time you read this paragraph, the Ohio River Valley Water Sanitation Compact will become effective. This Compact commits 8 states, comprising the Ohio River system, to a program of stream pollution abatement. To aid in carrying out the Compact a "Symposium on Water and Waste Treatment" will be held on October 16, 1948, in the Engineering Society Headquarters Building, Cincinnati, Ohio, for the purpose of providing a medium for disseminating the technical information essential to the solution of stream sanitation problems. For further information, write to Robert C. Head, Publicity Representative, American Institute of Chemical Engineers, 795 Greenville Avenue, Glendale, Ohio.

CANADA'S PUBLIC HEALTH FILM SURVEY

Supplement 3 of the *Medical and Biological Films Catalogue*, of the National Film Board of Canada, brings up to date the master list published in March, 1945, and two subsequent supplements published in July, 1946, and March, 1947. As with the previous lists, the films are classified according to the public health specialty such as industrial health and safety, cancer, personal hygiene, with the names and brief descriptions of specific films under each heading, also a comment of the suitability of each film for certain purposes. Ad-

ditional information may be obtained from the Distribution Officer, Health and Medical Films, National Film Board, Ottawa.

NEW ANTIBIOTICS DIRECTORY

Second edition of *Antibiotic Substances, Their Biological and Chemical Properties*, has recently been published by the antibiotic section in the Division of Research Grants and Fellowships, National Institute of Health. It contains current material on source, biological activity, unit, potency, and miscellaneous properties of more than 150 antibiotic substances ranging alphabetically from actidione to viridan. The compilation includes a number of unnamed factors, as well as named chemotherapeutic agents from non-microbial forms (quercetin, tomatin, etc.). First edition of the guide was published early in 1947.

NEGRO HEALTH AND MEDICAL CARE

In January the Health and Medical Care Collection of Meharry College was a year old. By way of celebrating its first birthday it published an annotated list of books, periodicals, pamphlets, leaflets, and articles relating specifically to the health of the Negro. With the coöperation of state health departments, national organizations, and individuals the Collection now numbers nearly 500 items.

Thomas A. LaSaine, M.D., the director, renews his invitation to share with this Collection available material concerning the health of the Negro. The address is Health and Medical Care Collection, Meharry Medical College, Nashville 8, Tenn.

DR. NORTON SUCCEEDS DR. REYNOLDS AS NORTH CAROLINA STATE HEALTH OFFICER

The retirement of Carl V. Reynolds, M.D., Secretary and State Health Officer of North Carolina, Raleigh, as of July 1, 1948, has been announced. Dr.

Reynolds will move to California and live in Altadena.

John W. R. Norton, M.D., M.P.H., of Chattanooga, Tenn., has been appointed to succeed Dr. Reynolds. Dr. Norton is a native of North Carolina, born in 1898, a graduate in medicine of Vanderbilt University in 1928, and with a Master's degree in Public Health from the Harvard School of Public Health in 1936. Dr. Norton served four years as Health Officer of the City of Rocky Mount, N. C., and served for several years with the North Carolina State Board of Health in the Divisions of County Health Work and Preventive Medicine. Dr. Norton served in the Army Medical Corps during World War II, since which time he has been Chief Health Officer of the Health and Safety Department, Tennessee Valley Authority, Chattanooga, Tenn.

DEATH OF DR. RUPERT BLUE

Rupert Blue, M.D., Ex-Surgeon General of the U. S. Public Health Service, died on April 12 in Charleston, S. C., at the age of 80. Dr. Blue retired in 1932 after 39 years in the Service, 12 of them as Surgeon General by appointment of President Taft in 1912 and reappointment by President Wilson in 1916.

Dr. Blue was noted for his bubonic plague campaigns in San Francisco in the early 1900's. He conducted extensive rat extermination drives there. During the first World War he was adviser on sanitation for military establishments in the United States. In 1923 he was American delegate to the Opium Conference of the League of Nations.

Dr. Blue became a member of the American Public Health Association in 1912 and a charter Fellow in 1922.

VIRGINIA'S MODEL ALCOHOLIC CARE BILL

The Virginia Legislature, one of the few that meet in the even numbered

years, has enacted a bill that sets up a Bureau of Alcohol Studies and Rehabilitation in the State Department of Health. Including an appropriation of \$200,000 for the biennium, the new law places the initial responsibility for the study and treatment of alcoholics upon medical schools and hospitals.

The first of several state research centers will be located at the Medical College of Virginia in Richmond where patients will receive both hospital and clinic care.

In reporting the Virginia law, Joseph Hirsh, Acting Director of The Research Council on Problems of Alcohol, said it would "undoubtedly serve as a model for the rest of the country." He pointed out that none of the other seven states that have already established medical programs for the care of alcoholics provides such an integrated program as that of Virginia.

EDUCATIONAL OPPORTUNITIES IN INDUSTRIAL HYGIENE

Industrial Hygiene Newsletter for April, 1948 (Vol. 8, No. 4), has a list of schools that give complete courses in industrial hygiene. Classified into the 9 U. S. Public Health Districts and into courses for physicians and dentists, nurses, engineers, and chemists, this list gives the name and address of the school and a short description of the courses, the time required to complete them, and degrees offered.

The Industrial Hygiene Division of the U. S. Public Health Service, which publishes this monthly *Newsletter*, carefully warns that the list is not a complete one. It is recommended to readers, however, as the most complete such listing that has come to hand.

PUBLIC HEALTH SECTION OF EXCERPTA MEDICA

Excerpta Medica, the project for abstracting the world's medical literature was mentioned in the August, 1947,

vacated by Dr. Scheele. Dr. Heller's position in the Division of Venereal Diseases will be assumed by Dr. Theodore J. Bauer who is at present on duty with the Chicago Board of Health as municipal venereal disease control officer.

INSTITUTE IN PUBLIC HEALTH ADMINISTRATION

The University College of Northwestern University, in coöperation with the U. S. Public Health Service, has announced a two week Institute in administration for principal administrative officers of state and local health departments. The Institute, July 12-23, will concern itself with administrative problems, and its registration is limited to 40 persons who must be health officials with managerial responsibilities.

The Institute was planned at an earlier regional conference of state and local health officers to meet gaps in the health officer's knowledge of such items as press and public relations, personnel administration, budget presentation, etc.

Registration fee for the Institute is \$100, of which \$10.00 must accompany registration request. Provision will be made for room and meals in Abbott Hall of the university at \$60 per person for the period. Application should be made before June 21 to the University College, Northwestern University, 710 Lake Shore Drive, Chicago 11, Ill.

"THE AMERICAN ENGINEER" UNDER NEW MANAGEMENT

The National Society of Professional Engineers announces the appointment of Franklin F. Page as Editor of the *American Engineer*, the monthly publication of that Society. Prior to joining the staff of the NSPE, Mr. Page had had considerable experience in newspaper work and has been editor of *Constructor and Engineer*, a publication serving the northwestern part of the United States.

PERSONALS

Central States

RICHARD F. BOYD, M.D., M.P.H.,* who has served for some years as Chief of the Division of Local Health Administration, Illinois State Department of Health, Springfield, Ill., has resigned, effective May 17, to accept a position of Medical Officer, Welfare and Retirement Fund, United Mine Workers of America with offices at 900-15th Street, N.W., Washington 5, D. C. In this capacity Dr. Boyd will be associated with R. R. SAYERS, M.D., who is Chairman of the Medical Advisory Board, and who is responsible for developing plans for the medical care and hospitalization of approximately 400,000 bituminous coal miners in 26 states.

DORIS G. CHANDLER, M.P.H.,† has been appointed Director of Health Education of the National Society for the Prevention of Blindness, New York, N. Y. For the last few years she has been Executive Secretary of the Metropolitan Health Council of Dayton and Montgomery Counties, Ohio.

CHARLES T. DOLEZAL, M.D.,† has been appointed Assistant Director and Secretary of the Council on Professional Practice of the American Hospital Association, Chicago, Ill., to succeed HUGO V. HULLERMAN, M.D.,* resigned. Dr. Dolezal was formerly Superintendent of City Hospital of Cleveland, Ohio.

WINSTON H. TUCKER, M.D.,* Commissioner of Health of Evanston, Ill., represented the A.P.H.A. at a meeting on April 5 and 6 on a Subcommittee of the American Medical Association Council on National Emergency Medical Service, for the purpose of planning for the most effective use of the overall medical resources of the nation in case of another national emergency. HAROLD S. DIEHL, M.D.,* Dean of the University of

Minnesota School of Medicine, Minneapolis, is Chairman of the Committee.

JOSEPH R. WAGNER, widely known in the fields of biochemistry and nutrition, has joined the staff of the Quartermaster Food and Container Institute for the Armed Forces, Chicago, Ill., as Chief of the Fruit and Vegetables Branch, Food Development Division. He was formerly head of the Nutritional Research Section in the General Laboratory of Libby, McNeill & Libby, Blue Island, Ill.

E. EUGENE WEHR, M.D., is now Assistant Health Commissioner in the Cincinnati, Ohio, Department of Health. WATSON DERSHAM† recently took up his duties as Health Educator of the Department.

WALDO W. WILMORE† has been appointed Associate Executive Secretary of the Kansas Tuberculosis and Health Association, Topeka. He was formerly Personnel Officer under FLOYD C. BEELMAN, M.D.,* Kansas State Board of Health.

E. V. THIEHOFF, M.D.,* has been appointed Professor and Head of the Department of Public Health and Preventive Medicine of the University of Kansas, Lawrence. He resigns as Commissioner of the Peoria City, Ill., Health Department on April 1.

Eastern States

STANHOPE BAYNE-JONES, M.D.,* who is President of the Joint Administrative Board, New York Hospital-Cornell Medical Center, New York City, has been awarded the insignia of Honorary Commander of the Military Division of the Most Excellent Order of the British Empire. The presentation was recently made in Washington by Lord Inverchapel, Britain's Ambassador.

CONRAD BERENS, M.D., of New York City was elected President of the Pan

American Association of Ophthalmology at the Third Pan American Congress of Ophthalmology held in Havana, Cuba, January 4-10.

ELSIE M. BOND has retired as Assistant Secretary of the State Charities Aid Association, New York, N. Y., after 25 years of service with the Association. Miss Bond served as the legislative representative of the S.C.A.A. in Albany during the administrations of Governors Alfred E. Smith, 1923-1929; Franklin D. Roosevelt, 1929-1932; Herbert H. Lehman, 1933-1942; and Thomas E. Dewey, 1943-1948.

THOMAS E. CONNOLLY was recently appointed Executive Secretary of the Onondaga Health Association, Syracuse, N. Y., to succeed ARTHUR W. TOWNE, retired recently as Executive Secretary of the Association after 24 years of notable service.

VLADO A. GETTING, M.D.,* was reappointed April 7 as Commissioner of Public Health of Massachusetts by GOVERNOR ROBERT F. BRADFORD. Dr. Getting, who is also President of the State and Territorial Health Officers Association, was first appointed to his present post in 1943 after having served as Worcester City Health Officer.

CUSHMAN D. HAAGENSEN, M.D., Associate Professor of Surgery at Columbia University's College of Physicians and Surgeons, New York, N. Y., has been named Coördinator of Cancer Teaching for the college's cancer research program. He is developing a project on cancer research designed to obtain close coöperation among major divisions of the university's medical sciences and clinical departments.

JOSEPH HIRSH,* who has been on leave of absence to WHO, has returned to the Research Council on Problems of Alcohol, New York, N. Y., and is now its Acting Director, following the

resignation of LYMAN C. DURVEA, M.D.,* to return to active service with the U. S. Army Medical Corps. Mr. Hirsh also serves as consultant to WHO.

THEODORE G. KLUMPP, M.D., President of Winthrop-Stearns, Inc., New York, N. Y., was elected President of the American Pharmaceutical Manufacturers Association at its recent annual convention in Havana, Cuba.

ESMOND R. LONG, M.D.,* Director of Medical Research and Therapy, National Tuberculosis Association, and Director of the Henry Phipps Institute, Philadelphia, Pa., has been named Editor-in-chief of the *American Review of Tuberculosis*, official journal of the National Tuberculosis Association's Medical Section, The American Trudeau Society, to succeed the late MAX PINNER, M.D.

WALSH McDERMOTT, M.D., Associate Professor of Medicine, Cornell University Medical School, New York, N. Y., has been appointed to the newly created post of Managing Editor of the *American Review of Tuberculosis*, New York City.

GORDON W. MOLYNEUX,* formerly Supervising Milk Inspector for the Westchester County, New York, Department of Health has resigned from the county service to manage the Rock Gate Dairy Farm, Bedford Hills, N. Y.

HOWARD A. RUSK, M.D.,† New York, N. Y., received the first annual Survey Award for "an imaginative and constructive contribution to social work" on April 22, for his outstanding work in translating into civilian life what was learned about rehabilitation in the armed forces. The award was presented by EDUARD C. LINDEMAN, M.D., for *The Survey* Midmonthly during the 75th Anniversary Meeting of the National Conference of Social Work held in Atlantic City, N. J.

AUSTIN SMITH, M.D.,* Secretary of the Council on Pharmacy and Chemistry of the American Medical Association, Chicago, Ill., has been appointed Science Editor of *American Druggist Magazine*, New York, N. Y. Dr. Smith will continue his work with the A.M.A., and will maintain his office at the A.M.A.'s headquarters in Chicago.

Southern States

DANIEL BLAIN, M.D., formerly Chief of Neuropsychiatric Service for the Veterans Administration, Washington, D. C., has accepted the newly established position of Medical Director of the American Psychiatric Association.

FRANCIS G. BLAKE, M.D., Sterling Professor of Medicine at Yale University, New Haven, Conn., has been appointed to head the Medical Science Committee of the Federal Research and Development Board, Washington, D. C. Dr. Blake is a member of the Lasker Awards Committee, A.P.H.A.

JOHN M. DAVID† has accepted a position with the Layne-Atlantic Well Company, Albany, Ga. He was formerly Regional Engineer with the Georgia State Department of Public Health in the Southwest Region of Georgia.

LAWRENCE MACHEMER FISHER,* Sanitary Engineer Director of the Public Health Service, was recently appointed by PRESIDENT TRUMAN to the Interstate Commission on the Potomac River Basin. Other commission members serving by presidential appointment are C. C. BURGER, Department of the Army, and ABREU WOLMAN,* Johns Hopkins University.

ROBERT A. HINGSON, M.D., has been

* Fellow A.P.H.A.

† Member A.P.H.A.

Some Concrete Problems of Health Administration*

A GROUP of outstanding health administrators (on state, city and county levels) were asked to prepare for

* Special Review article prepared at the request of the Editorial Board.

the JOURNAL brief statements with regard to specific problems of administration which they had faced during the past year. The general significance of these contributions is discussed editorially on page 1008 of this issue.

Staff Education in Chicago

HERMAN N. BUNDESEN

During the depression years, the food inspection section of the Chicago Health Department had been operating with a totally inadequate force, due to insufficient appropriations.

Previous to the passage of the appropriation bill for the year 1947, it was the practice of the Board of Health, in submitting budget estimates for each year, to ask for additional personnel for the food inspection section in order to maintain a reasonable inspection standard. However, these requests for funds to employ additional personnel went unheeded year after year.

During the year 1946, the U. S. Public Health Service made a survey of the activities of the Health Department of the City of Chicago, together with other official and voluntary health agencies

in the city and Cook County. Among the recommendations made in the report of that survey was that the food inspection section be provided with added personnel, and that a revision of the food control ordinance, based on the requirements of the U. S. Public Health Service recommended code, be adopted by the City Council. As a result of this report, twenty-five additional food inspectors and three additional supervisors were provided, and the revision of the *Municipal Code* was made.

The coming of new inspectors upon the staff necessitated a change in the existing in-service training program for the purpose of teaching these new men the fundamentals of sanitation and inspection technique.

At about the time these men were first

employed, a program of food handler education was being carried on in cooperation with the Chicago Restaurant Association. Newly appointed food inspectors were first required to attend these food handler courses, in order that they might acquaint themselves with what was necessary from the food handler's standpoint. Following this, an intensive course in ordinance requirements and recognition of satisfactory compliance was carried on. Instructions were given especially as to the public health reasons for ordinance requirements. Inspectors were required to spend some time in the laboratory to observe the method of making plate swab counts and to learn the technique of making swab tests.

Newly appointed inspectors were sent out in groups of three with a supervisor accompanying each group, in order to observe the supervisor's method of making food inspections; then, after a week, the new men made the inspections themselves under the personal observation of the supervisor. Following this part of their training, they were required to spend at least 2 weeks in the field with qualified inspectors, and in some cases more time, until they were able to make a satisfactory inspection and report. The In-Service Training School has continued to operate after the new inspectors completed this training and were out working on their own responsibility. Weekly sessions of the school were held to give them specialized training on such subjects as milk inspection, meat inspection, poultry inspection, refrigera-

tion of foods, food poisoning, disinfection of utensils, plumbing and back siphonage, particularly as applied to restaurants and hotels, construction of dishwashing machines, courtesy and tact in dealing with the public, fumigation of foods for destruction of vermin infesting the foods, procedures in license approval, preparation of drastic measures where warranted, and other subjects with which the food inspector should be familiar.

It is the opinion of the Chicago Health Department that food inspectors do not become efficient merely by grace of an appointment. In addition to such knowledge and experience as a man may have when he receives an appointment, he must also have a will to learn and the capacity to absorb and use the knowledge that is given to him in the In-Service Training School and by supervisors in the field.

The food inspector, on entering a food establishment, is the representative of the Board of Health. As such, he should be able to conduct inspections in such a way as to render to the citizens of his community all the service which the city ordinance requires the head of the Health Department to render in food establishments and to reflect credit upon the department which he represents.

There is no set formula by which one can convert a new inspector from raw, untrained material to the ideal which is needed. It is only by constant education within our own service that this goal can be reached.

Housing the Health Department in Detroit

BRUCE H. DOUGLAS

Local conditions will have much to do with the housing of the health department. Much will depend too on whether

it is a small or a large health unit, a state health department, a county unit in a rural area, or a municipal depart-

ment serving a populous urban community. It would seem, however, that there are certain principles that should prevail in providing housing for a health department in order to contribute good public health administration in the best interest of the people.

Too often the space provided for a health department is some inaccessible, reconverted building or basement location which is assigned because of limited budget or lack of vision by public officials. Frequently there is little appreciation of the needs of the health department or of the place it should occupy in the area to be served.

Of course it is to be conceded that the housing of a health department is not as important as the matter of having well qualified personnel, but nevertheless, appropriate housing will make for better service and greater appreciation by all concerned, including the public, as to the importance of the role the health department plays in the community.

With new public building programs under way or projected, it is timely to give consideration to this matter. Several large cities are planning new provisions varying from a separate building for public health administration to combination with one or more other governmental departments or, finally, inclusion in a large municipal building where all administrative offices of the city or the city-county government will be housed.

There are points in favor of each of these arrangements as well as points against them. It is also true that variations in the functions performed by different health departments may affect

the arrangements for housing. For instance, when the health department is responsible for the operation of a hospital or hospitals, it may be desirable to have the administrative offices of the health department located in or near the hospital plant.

The principal point in favor of a municipal health department being housed with other city administrative offices is the convenience afforded those who must secure certain permits, license approvals, and similar records or information, often related to other public departments, so that if housed together, the individual visitor can transact all his business within one building.

Much of the work of a health department, however, is not related directly to other departments of government. For example, services to physicians, provision for clinics, and issuance of vital records make it highly desirable to have these activities housed within easy access for those coming to the health department for such services. In addition, the ease with which field staff may come and go in carrying out their duties must be given consideration. Of course, in a large city some services can and should be decentralized by providing health centers for certain functions in locations where they are near the people needing the services and out of which the field staff may more readily work. These may profitably be located in or near hospitals or medical centers.

There is therefore good justification for the health department having its own building properly located, thereby emphasizing the importance of its services as well as making possible greater accessibility for those it serves.

Coöperation with Voluntary Organizations in Montgomery County, Maryland

V. L. ELLICOTT

The year 1947 has shown no decrease in voluntary organizations. Each one still remains a pressure group for a special interest. The health officer's attitude is usually one of caution so as to keep these people from getting out of hand. My suggestion is to take the risk of encouraging them and working with them in order to get the advantage of their public support.

The progressive health officer does not want a static health program but one geared for growth, the growth being directed toward unmet health needs. So few health departments approach adequacy at present that provision for growth should be a basic principle of organization. This means successive increases in personnel and budgets. The simplest way to obtain them is by direct request of the health officer to the county commissioners or other appropriating body, the appeal being based on a clear, logical statement of needs. This appeal often fails, however, because the county commissioners expect new proposals to be supported by public interest as well as logic. Can the health officer utilize voluntary organizations to gain this support?

Since voluntary organizations may be pulling in different directions, the health officer's problem is to get them to pull together and pull with him. In Montgomery County we believe we have found an effective way of doing this. Each organization is encouraged to take

an interest in the general county-wide program in addition to its special interest. Each of our eleven local public health lay committees, for example, does this by recognizing the dependence of the local public health nurse on the county nursing group. As a result, local committees vigorously supported the 1947 successful drive for more adequate nursing salaries. The Tuberculosis Association and many other similar groups are joining in a concerted effort to secure a new county health center in Rockville. The most important part of this county-wide interest, however, is the agreement among the organizations and the Health Department as to what the principal health needs are and what is the order of their importance. We depend largely upon the American Public Health Association's *Evaluation Schedule* for this important step. The *Schedule*, we point out, represents the opinions of leading nation-wide health authorities. It therefore has a common appeal to all intelligent public spirited citizens, the same appeal as the recommendations of an important survey. It also proves that the current proposals for meeting the needs are something more than the special interests of the health officer. This approach—agreement between voluntary agencies, other citizen groups, and the health officer—has one other advantage—it works better with each year of usage.

Procurement of Personnel in Massachusetts

V. A. GETTING

Today health agencies are faced with a critical shortage of professional and technical personnel. An analysis of the factors for this ever increasing shortage reveals some of the major difficulties which make positions in public health unattractive to candidates seeking fields for professional training. This is true in spite of the fact that the words "public health" are more in the mouths of the everyday citizen, and the importance of health is better recognized than at any time previous. The obstacles in procurement of personnel must be overcome in order to procure staffs of adequately trained and experienced workers. Some of these difficulties may be summarized as follows:

1. Inadequate compensation — Although many health agencies have increased their salaries, the new salary schedules are still far below those which exist in the federal government agencies, in private practice, and in industry. Further substantial increases are indicated to overcome this obvious shortage.

2. Procurement policies—Merit systems and civil service procurement facilities cannot be relied upon exclusively. Health agencies, particularly state health departments and large voluntary agencies, must carry on detailed procurement programs from the secondary schools, professional and technical schools, to the public as well. Special personnel may be assigned to such programs.

3. Political interference—Freedom of exercise of the responsibilities of the health department is an absolute necessity. This must be unhampered by political interference if these positions in public agencies are to attract capable administrators. Too often administra-

tors drift from public to voluntary agencies because they are unable to discharge their duties without regard for political policies.

4. Dramatizing the job—General information which is both current and interestingly presented must be supplied to the public and the professions in order to make the positions and the work of health departments known. Today, as a matter of fact, only a relatively small number of physicians realize what health departments are doing. The significance of the work and accomplishments of health departments must be so dramatized and pictorialized that high school and college students will become enthusiastic about seeking positions in this field.

5. Security of tenure—With forty state health officers being replaced within a period of 5 years, it becomes apparent that the top administrative positions in public agencies are insecure. Because of this insecurity, positions of staff members become less desirable. With every replacement of a state health officer, policies are revised and responsibilities shifted, and there result obvious limitations in promotions and lack of continuity in the content of programs. Thus, measures must be taken to insure security of tenure at all administrative levels.

6. Merit system limitations — Although the primary purpose of merit and civil service systems is the procurement of qualified personnel, too often such systems, especially those established many years ago, offer serious limitations in the procurement of personnel. The merit system has too often become a method for protecting the employee rather than the service. Thus, veterans'

preference, residential requirements, and lack of educational qualifications may actually be deterrents to the procurement of adequately trained and experienced personnel. Some method must be found whereby the procurement work of merit systems is improved, so that promotional advancements may be offered to employees, and the limitations of lack of educational requirements, total veterans' preference and residential requirements may be limited, modified, or, if necessary, removed.

7. Retirement, vacation and sickness benefits—As human beings, employees have certain rights which must be respected and certain privileges which must be offered in order to attract them to positions in public service. The provision of adequate retirement systems, vacation allowances, and sick leave are

necessary, especially in today's shortage of personnel. A specialty board for physicians in public health may be an added inducement in the procurement of adequate personnel.

8. Physical facilities—Cheerful, well furnished, well lighted and ventilated offices are a necessity to any department. Too often a health department is located either in a basement or on a top floor of a public building, in the least desirable quarters available.

9. Recognition of services—Professional and technical workers require recognition in the form of credit and praise both in professional and public circles. Ample opportunities should be provided to reward faithful and hard working health department employees in recognition of their work and accomplishments.

Financing Local Health Departments in Florida

F. M. HALL

In 1911, Dr. Hermann M. Biggs,¹ then Commissioner of Health of the City of New York, said, "Public health is purchasable. . . ." He might have added, "but not at bargain-basement prices."

Too frequently state health departments, in their overzealous ambition to see local health service established in all areas of their jurisdiction, have sold the services at bargain-basement prices to the local appropriating bodies, assuming that, once the local unit was established, it would sell itself to the community. However, if a health department is to render in the community the worth while services expected, from the beginning, the financial support must be adequate. If this adequate financial support is not available, the local health department must depend upon poorly

trained individuals to render public health services to the community. This procedure results in poor services to the people and an undesirable impression given to the local governing body as to quantity and quality of work. Thus, a health department that is inadequately financed from the beginning is unable to render the services expected, and the local governing body and the community are unfavorably impressed by such services. So, when additional funds are sought, the appropriating bodies are not interested in increasing the appropriations.

The local governing body must be given, and must assume, full responsibility for its health department, both financially and for the services to be rendered, with a minimum of supervisory or advisory control from the state and

federal levels. To secure adequately financed health services in a community there must be local autonomy, but it should be impressed upon the local officials of the community that with local autonomy goes a local responsibility—a responsibility to finance its health services adequately; and a responsibility, after such financing, that services be rendered to the community in a manner that is in accord with good public health practices.

A goodly number of local health officers today find themselves in a situation that is rather difficult to meet. The individuals responsible for the establishment of the initial budget for the area based their estimates upon a monetary situation that is entirely different from the present-day inflationary period. Emerson² and his Committee on Administrative Practices used as a guide an overall cost of \$1.00 per capita for complete coverage of six minimum full-time services.

With our ever-broadening concepts of public health, one would readily come to the conclusion, even in a non-inflationary period, that \$1.00 per capita would be inadequate in financing a program based on these six phases.

Even to carry a program embracing the basic requirements, plus a few additional programs that are needed in any area, if we consider the inflation of the day, the minimum total per capita should be at least \$2.50, with \$1.00 as local contribution. Since the services of a health department are available to the entire health jurisdiction which it serves, the local support for such a health department should come from the governing body that directs the entire health jurisdiction unless special services are requested by a municipality that is within the area. Then, of course, those special services should be financed by the municipality concerned.

When the Alachua County Health De-

partment was established in 1944, an agreement was made by the Director of Local Health Service and a local committee spearheading the formation of this health department that 53 cents per capita locally would be adequate. The area would have, after state and federal contributions, \$1.11 per capita for public health services. As inflation has progressed over the years, the governing body has always reminded the committee and the Director of Local Health Service, of their original commitments. It is felt that many health officers find themselves, through no fault of their own, bound by such commitments. Even the governing bodies themselves have been caught short by the ever-increasing cost of government.

The health officer has open to him two courses:

1. Reduce staff with a resultant curtailment of program in order that salary increases may be met.
2. Secure additional funds to maintain an adequate public health program.

The latter method is preferred. The services rendered must be maintained at the present levels because the general public, having once become accustomed to an efficient public health program, would not understand why these services were curtailed.

The method of securing additional appropriations to augment the local budget must be determined by the health officer in his own respective area. He should be, and is, better informed of the local conditions than any other individual. If the health department has rendered a service that has been adequate and efficient, the difficulties in breaking down the barrier that was once built is much easier than if, from the beginning, the services of the organization have been considered inadequate.

It is well before an attempt is made to increase the appropriations, to evaluate your own health program both as to services rendered and allocation of

time to each service. This evaluation should include the accomplishments of the department. If it can be shown from such an evaluation that progress has been made, then the health officer has in his possession one of the strongest arguments that can be presented, a

local governing body in a justification of his request for additional funds.

Fiscal Relationships Between the State and Local Health Departments in California

W. L. HALVERSON

The question of the fiscal relationship between the state and local health departments is squarely before us in California. This is occasioned by the passage of the Public Health Assistance law providing \$3,000,000 for local health services, which became effective September 19, 1947. This appropriation is in addition to approximately \$1,000,000 of federal funds available for local health services.

Federal funds have been allocated largely on the basis of the extent of the problem in the various areas rather than on a formula basis. Density of population, percentage increase in population, morbidity and death rates for specific diseases such as venereal disease and tuberculosis, infant and maternal mortality rates, have all been factors in the decision as to the allocation of the various federal funds available. However, these factors have not been crystallized into a definite formula. Local health departments organized during the war period were allotted relatively large amounts per capita. In a survey of the situation, allocations to local health departments were found to vary from nothing to approximately 50 cents per capita. This can be defended during periods of stress such as the recent world war, but not on a continuing basis.

The formula for the allocation of the \$3,000,000 state fund for local health services is written into the law. Each county receives a basic allotment of \$16,000 or 60 cents per capita, whichever is less. The remainder, after subtraction of $7\frac{1}{2}$ per cent of the total for administrative and consultative services and training, is allocated to health departments meeting standards on a straight per capita basis.

In effect, counties with a population of 26,000 or less, and meeting minimum standards, receive approximately 82 cents per capita regardless of whether they operate individually or as a part of multi-county health units. Larger health jurisdictions receive a gradually decreasing per capita allotment, so that the metropolitan areas receive between 22 cents and 23 cents.

With this fairly liberal allocation of state funds, especially to the smaller health jurisdictions, we ask ourselves the question, "Should not a large proportion of the federal funds available for local health services also be allocated on a formula basis?" This administrative question has not been answered.

Our Public Health Assistance Act officially sets up a California Conference of Local Health Officers. This Con-

ference has at present four standing committees:

1. Administrative Practice
2. Fiscal Affairs
3. Personnel
4. Records and Reports

By law, the Conference must approve standards for local health service before establishment by the State Department of Public Health. We now propose that this Conference shall actively participate in the development of policy regarding the allocation of the federal funds. To this end, the Committees on Administrative Practice and Fiscal Affairs have developed proposals, with the assistance of the Divisions of Adminis-

tration and Local Health Service of the State Department of Public Health. These proposals were submitted to a meeting of the Conference, in February.

This department subscribes to and promotes the concept that local health departments should have a high degree of local autonomy. In order to accomplish this, it is essential that local health officers actively participate in the planning and execution of the total statewide public health program. It is anticipated that the present California law will go far in facilitating close working relationship between the state and local health departments, and will preserve the basic concept of local control.

Program Plans for Public Health Action in New York State

HERMAN E. HILLEBOE

One of the most important administrative problems of an official public health agency is the creation of orderly and well defined procedures and plans for public health action. Such a master working plan should have sufficient flexibility to permit such changes as circumstances and new knowledge require, but still present a uniformity of principle to which all public health workers can unanimously subscribe.

During the past year, the administrative staff of the New York State Department of Health has been engaged in an intensive review and evaluation of every program carried on by the department. The knowledge, experience, and thinking of the men engaged in and responsible for rendering health service to the public were presented in frequent conferences. Eventually, through change and interchange, through criticism and attack, through accumulation of data in all fields, specific public health program plans have been developed.

It should be recalled that a general health program in a nation, state, or local community is no better than the quality of the special programs which compose it. The emphasis on each disease should be determined by the seriousness of that disease in the particular area involved, making each special attack on a disease strong, effective, and well financed in relation to the problem. This is the surest way of building a general health program that will meet the needs of all the people and that will be accepted by them and permanently supported.

Before any disease which affects the general public can be controlled or eliminated, it is essential that professional public health personnel attack the problem under three main headings:

- A. The need for the program
- B. Objectives to be achieved
- C. Functions and techniques to be used to gain the objectives

When these three categories are ade-

quately considered, it is interesting to observe that public health program planners arrive at a remarkable uniformity of procedure and policy. The conventional approaches to public health administration and action; such as, control of communicable diseases, maternal and child health, vital statistics, nursing service, health education, and environmental sanitation, undergo a functional regrouping so as to permit an enlarged scope of program and the application of multiple techniques that will bring improved health services to the people.

To reach our important goals, particularly in providing health services in local communities, an official public health program should have three specific objectives:

1. Prevention and control of mass diseases
2. The collection and analysis of vital records
3. The maintenance and improvement of a healthy environment

Such specific objectives postulate certain well defined activities and functions and the application of definite techniques. These techniques can be described briefly as follows:

1. Study the extent of the public health problem. This includes the making of a complete survey of a community either by state or local personnel or by both. It will be necessary to review this evaluation at regular intervals, possibly as frequently as every year.

2. Recruit, train, and use competent personnel. Plans for improvement of local health services can be carried out only if adequate numbers of well qualified physicians, nurses, sanitary engineers, sanitarians, dentists, physiotherapists, health educators, medical-social workers, nutritionists, and others are available for employment. With the present-day shortage of personnel this requires that health departments obtain recruits who are untrained and give them the necessary academic or field training and experience to perform the duties of the several positions. Such training should not cease with employment but provision should be made for continuous-on-the-job training to keep the employees informed of newer methods and techniques, as well as to qualify them for more responsible positions.

3. Provide adequate modern quarters and the necessary equipment and tools of the profession.

4. Demonstrate the newest methods and consult with all participating groups. Frequently, local appropriating authorities "must be shown." Demonstrations can be given through loan of state personnel and equipment. Unofficial agencies may participate in financing a program on a demonstration basis. Frequently, the "know how" in public health is essential in the starting of a new program and those with previous experience may be loaned to assist the local community in the inauguration of a new activity.

5. Provide financial assistance. The benefits of public health activities are *not on the individual community basis*, and provision must be made for the equitable distribution of the cost of public health work.

6. Do basic and applied research. The inception of new progress requires a trial and error period. This might best be confined to one or a few areas, and, when techniques and procedures are developed, these can be given to other communities with reasonable assumption that there will be considerable saving in time, effort, and money.

7. Coöperate with other agencies, both public and private. Health, both from the individual and community standpoints, results from the coöperative efforts of many official and unofficial agencies.

8. Develop and carry on extensive health education activities.

9. Obtain laws and prepare regulations that will permit the establishment and increase the effectiveness of local health services.

10. Analyze and evaluate public health programs to determine their effectiveness, achievements, and the attitude of the people toward them. This analysis should preferably be done annually. Frequently, it is advisable to have such analysis and evaluation performed by someone outside of the department concerned. For instance, the analysis and evaluation of a county health department might well be performed by members of the state health department. Self-analysis and evaluation is likewise important, and each administrator should make such analysis of his own activities and adjust his program accordingly.

These objectives and techniques are as applicable to public health work in Texas, California, or any other state as they are to public health in New York State.

Allocation of Funds to Local Programs

G. F. MOENCH, OAK RIDGE, TENN.

The subject, "Allocation of Funds to Local Programs," is assumed to apply to the adequate financing and support for the extension of local health units for the nation.

It is also assumed that patterns, methods, and formulae are available. Funds are now currently available; therefore, this discussion deals with some dangers and offers suggestions for an action program relative to responsibility of the three potential sources of funds: local, state, and federal.

The financing of local health units began with an effort by the local community and has remained largely a local responsibility. In the last twenty years, certain state governments have made feeble attempts to assist local communities in the financing of local health departments. And, today, several states are doing an admirable job helping local communities.

The principle of federal assistance to states is well established. Modest sums have been provided and earmarked to deal with special health problems, such as venereal disease, tuberculosis, nutrition, and cancer control. Relatively little of this money has filtered down to the local health units development. It is high time that professionally trained people in public health unite their efforts to support a fundamentally sound plan for adequately financing local health units. Responsibility is at least half that of the local community in accordance with local financial resources, and the state and federal government must step in where the local level reaches the end of its ability to pay. Health services, both preventive and curative, cost money and are worth paying for. The need is pressing. Fast moving events of

this Atomic Age demand that we change the tempo of our thinking and movements.

There are three sources of danger, or factors to consider, in efforts to allocate funds and support to local health units: (1) Professional conventions and conferences have admirably discussed organization problems, including finance. For five years, these meetings have closed with no definite action. (2) Public health-trained people are conditioned to the belief that the growth and development of a local health unit is a long, slow process. In the light of present-day needs and knowledge, this dull, inert, negative, defeatist, smugly complacent attitude is a serious threat to the security of our nation. (3) The increased responsibility for new programs, the constant insecurity, the frustrating effect of heavy case loads on limited staff, leaves little time for constructive planning and adequate financing on a long-range basis. If we are to convince the consumer public that health services are valuable to the community, local health workers must believe wholeheartedly in health service goals and show by administrative action that public health cannot be compromised, neglected, shortchanged, or curtailed.

Several specific suggestions for overcoming some of our difficulties in allocating support of local health service units are offered for consideration.

First, public health workers must maintain within themselves the firm conviction that the principles of the entire program are essential, sound, and worth upholding against all odds. Ask the questions, "Do we really believe in the concepts of health practice that we are trying to instill in the consumer public?"

If so, are we functioning or working half as well as we know how? If not, what can we do ourselves to fit ourselves better to the job at hand?"

The second suggestion is the need for professional health administrators' association on a state-wide basis.

The third suggestion is coöperation with other professional and lay leadership by the organization of local health committees or councils. Many suggestions and patterns for this type of local health council are available from such organizations as the National Health Council, the American Medical Association, the National Congress of Parents and Teachers, as well as educational organizations.

The fourth essential is closer coöperation with voluntary and lay organizations as a means of interpreting financial needs and obtaining legislative support for the extension of local health units. Nearly every organization in the country has a health committee, a health interest, or a health program, and it is a responsibility of the local health unit to know just how the program can be integrated with that of the local health department to prevent an overlapping of services and wasting of resources.

The fifth specific suggestion is awareness of pending legislation, studying it as to objectives and source of introduction and support, following through with action to back it if favorable to community health services, and fighting it just as hard if it appears to be a threat to the health and welfare of the local community.

A most significant piece of federal legislation, which has a direct bearing on providing financial assistance from the

federal government to state health departments for support and extension of local health units for the nation, has been introduced into our Congress this year. This is the first time in history that federal aid bills have ever been introduced solely for the purpose of extending local health units. This bill is identified in the Senate as S-2189 and in the House as Joint bills H.R. 5644 and 5678, and is known as the Local Health Services Act of 1948. This legislation is initiated and sponsored by the National Congress of Parents and Teachers. Over forty-five other national professional, voluntary, and lay organizations, support the National Congress of Parents and Teachers in their introduction of the bill into the Congress of the United States of America.

It is suggested that each local health officer, and all others interested, immediately contact their state health officer and coöperate with him and the state and local Parent Teachers Association to follow the bill through its various steps to becoming a law, and to initiate local action and support at the proper time that will inform Congressional, Senate, and House committees of the needs for immediate passage of this legislation.

The need for favorable action on this bill is unquestionable. Regardless of how good the professional help and guidance in technical matters may be, there is a time when the assistance of lay consumer groups is essential. Consumers are voters and voters have a responsibility to inform their senators and representatives as to their wishes regarding health legislation.

Let us all go into action.

Amalgamation of Health Departments in Seattle and King County

EMIL E. PALMQUIST

The amalgamation of the administration and the combining of the clinics and the laboratories of the City of Seattle and of the King County Health Departments became effective September 8, 1947.

The idea of amalgamation in our state is not a new one since several of the first class and second class cities, some of them for many years, have pooled their resources with those of their respective counties to form districts or health units. Seattle, however, is the first large city (over 100,000 population) to begin such an amalgamation. A merger of the City and County Health Departments was first recommended in the book *Local Health Units for the Nation*. The impetus for the present amalgamation began in May, 1947, when the Health Officer of King County resigned with the recommendation that such an amalgamation be effected. The Board of Commissioners of King County requested recommendations from the King County Medical Society, which appointed a special committee consisting of three of its members, who after investigation recommended to the Board that they approach the City of Seattle and request consideration of an amalgamation of the City and County Health Departments. The Seattle Municipal League also made a study of the problem and approved the plan and recommended to both the city and county governments that they get together and work out a plan of amalgamation as far as possible under existing laws. The state at present has no enabling legislation providing for combined health units for cities over 100,000 popu-

lation. On the other hand, there are no state laws making it illegal to work out a combination by agreement. The existing law covering smaller cities and counties was passed as recently as 1945 after several of the cities and counties in the state had been operating on a combined health unit basis for many years. There was a precedent, therefore, with which we had to work.

Since there is no law setting up a way of merging the two departments, it was agreed that the amalgamation would be worked out on the following basis:

The Director of Public Health for the City of Seattle was made Director for both the City and the County Health Departments.

The Division Directors of the following respective divisions of the City Health Department were put in charge of the same respective programs for the County Health Department:

- a. Acute Communicable Disease Control (Epidemiologist)
- b. Division of Tuberculosis Control
- c. Division of Venereal Disease Control
- d. Division of Maternal and Child Health Services
- e. Division of Public Health Nursing
- f. Division of Central Administration, which includes the Director's office combined with the Chief Clerk and his staff
- g. Director of Laboratories
- h. Public Health Education
- i. The Divisions of Sanitation of the City and County are kept on a separate basis, each with its own chief under the general direction of the Director of Public Health. They will be combined under the same administration at a later date.

The Division of Costs for the jointly employed people who are the administrative personnel indicated above, was

worked out according to the population ratio of 75 per cent for the City of Seattle and 25 per cent for King County. The population in the City being 470,000 and the population in King County outside of the City, being 155,000. Actually, what has taken place is the joint employment by the City and the County of the same people to carry out the administrative work and then on an agreement basis combining the clinics, leaving it up to the discretion of the Director of Public Health to use to the best advantage the available space of both departments and the assignment of the employees.

Enabling state legislation, now being prepared, is still needed to effect a complete merger. Many factors must be considered, among which are: that the city employees have civil service and retirement benefits, and the county employees do not; a plan for permitting a single budget and the pooling and disbursement of moneys from a single fund.

The above is a successful beginning. The amalgamation has removed much of the confusion, overlapping, and duplication which existed before, and is proving beneficial to both the City and the County.

Health Coördination in New Orleans

JOHN M. WHITNEY

In August, 1947, the Mayor of New Orleans decided that the city needed a cleanup campaign. He called in the Health Officer who first suggested that a citizens' committee be appointed, but at the same time recommended that some type of permanent organization be effected which would mobilize and utilize citizen participation in various health activities each year. Since there was a very effective organization of block leaders during the late war it was felt that a start could be made by reactivating this organization. Accordingly the war-time leader of the block organization, a prominent civic minded volunteer, was called in and she agreed to accept the job of securing the active participation of as many of the former block leaders as would respond. However, she was willing to do this only on the condition that a permanent organization be set up with funds available to provide office and clerical facilities as well as educational supplies. Neither she nor the Health Officer wanted to engage in the

stereotyped "annual cleanup" and then see the city lapse into the same old condition. It was further felt that the time and effort necessary to enlist wide citizen participation would not be justifiable for just a single project.

The Council of Social Agencies in New Orleans has a Health Division which includes the voluntary health agencies, and the professional groups, as well as the official health agency. This division has functioned as a health council in the accepted definition of such councils as a planning and coördinating group for community health. In addition, there is in the Council of Social Agencies a "Community Volunteer Service" whose function is to recruit volunteer workers for such hospitals, Red Cross programs, etc.

After much discussion and many conferences a "steering committee" was set up consisting of the Secretary of the Health Division of the Council of Social Agencies, representatives from each

of the nine voluntary agencies operating in the health field,* from the Association of Commerce, the Young Men's Business Club, the Junior Chamber of Commerce, the public and parochial school systems; the block system leader, the director of the Community Volunteer Service, and the Health Officer.

The city administration came through with a \$10,000 appropriation to the health department to implement the entire program. A coördinator with clerical assistance was employed and housed in the health department. This coördinator's job was to secure health chairmen from every woman's organization in town and to arrange for meetings with these chairmen, first to explain the purpose and planned functions of the "Health Council of New Orleans" (as it was then named), and then to funnel information and materials through the chairmen to their members. The chief purpose was to get approximately 100 groups working on the same program at the same time. Practically every one of these groups had health committees and was engaged at some time during the year in its own pet projects. It was thought that many projects of community-wide significance could be put into operation much more effectively by having everybody doing the same thing at the same time. The city clean-up campaign served as the first example, and was a "natural" because a hurricane descended on New Orleans at about this time (September, 1947), and there we had a most effective stimulus.

Since the purpose of this report is not to give an account of the activities of the Health Council, suffice it to say

that the clean-up campaign was accomplished by intensive publicity, with actual operations by both city crews and volunteers during a one month period.

The next thing we had to consider was how to keep alive the interest and active participation of all the groups concerned. It soon became apparent that there was considerable duplication by the Health Council with the Health Division of the Council of Social Agencies with respect to planning, and with the Community Volunteer Service in respect to direct services. Also, from the administrative viewpoint of the Health Officer, here was this "coördinator" and her staff standing out like a branch on the department and spending funds officially appropriated to the Health Department. Further, the Health Division of the Council of Social Agencies was justifiably disturbed over the developing situation. On the one hand the Health Council was composed of a much broader representation than the Health Division would ever have, such as women's civic clubs, auxiliaries, veterans' groups, church societies, etc. In addition, the Health Council program was designed to be one of direct services, such as actual distribution by group members of literature, rat poison, or any other service relating to a community-wide program. On the other hand, many of the women's groups in the Health Council were also a part of the Community Volunteer Service. But the direct services they were performing were limited to a few central points such as clinics and hospitals, and in addition did not include educational programs. So it was felt that there was a definite need for the services to be rendered by the Health Council, and the problem now was how to furnish these services without duplicating and overlapping the areas of operation of the Health Division of the Community Volunteer Service of the Council of Social Agencies.

We have proceeded to effect this re-

Crippled Children Society
Social Hygiene Association

organization by placing the paid staff of the Health Council in the division of health education of the Health Department. The name will be changed to some title such as "Citizens' Health Committee." An executive committee will be set up with representation from the professional societies, the voluntary agencies, and the official agency. To the Health Division of the Council of Social Agencies will still be reserved the planning and coördination of all community health, and it will act as an advisory committee to this executive committee. All organized groups, including the Community Volunteer Service, will then carry out the programs and policies as

determined by the executive committee with advice from the Health Division of the Council of Social Agencies.

The Citizens' Health Committee will be considered more as an organization to supplement official work of the Health Department in special programs.

During the period of reorganization two additional projects have been successfully carried out—food conservation in January, 1948, and a city-wide rat poisoning campaign in April, 1948. Other contemplated projects are chest x-rays on a city-wide basis, annual physical examinations, and any timely health programs projected on a national basis.

What's Happening to Malaria in the U.S.A.?

JUSTIN M. ANDREWS, Sc.D., F.A.P.H.A.

*Scientist Director, Deputy Officer in Charge, Communicable Disease Center,
U. S. Public Health Service, Atlanta, Ga.*

THE general decline of malaria in this country is believed to have begun during the last quarter of the 19th century,¹⁻³ some years before it was known how the disease is transmitted. At that time, malaria virtually blanketed the eastern two-thirds of the nation, except for the Appalachian highlands, and extended up the Central Valley of California.⁴ Its retreat has been interrupted, at least during the latter half of the intervening period, by resurgences in prevalence at such regular intervals that a 5 to 7 year cyclicity in epidemic manifestations has been postulated.^{4, 5} The last of these periods of enhanced transmission took place during the mid-1930's of this century. By that time, the principal areas of endemicity had contracted to the coastal plains and lime-sink sections of the southeastern states and the flood-plain areas of the lower Mississippi and its main tributaries. Since this last upswing, 12 to 14 years ago, reported malaria prevalence in the U.S.A. has decreased steadily as shown in the accompanying graphs (Figure 1). Making generous allowance for the traditional errors of omission and commission in malaria reporting, it is evident that consistent declines in recorded morbidity and mortality, unprecedented in their magnitude and

duration, have been in effect for the last decade or more. This downward trend is verified by the general testimony of residents and by special field studies^{6, 7} in areas where malaria has been highly endemic in the past.

What is the significance of this latest recession? Since 1935 there has been no reported increase in indigenous malaria case or death rates in the country as a whole. This indicates that the regular wave-like pattern of malaria epidemicity throughout the nation is not an immutable phenomenon. If the negative slope of the last 12 years' experience can be continued or accelerated, it can mean nothing more or less than the ultimate extinction of malaria in the United States. To exploit this trend, it is important to determine its causes, if possible, while they are still in effect.

Is malaria being treated out of existence? Has it stopped relapsing or has man become generally refractory to infection? Have infectible anophelines become so few that transmission is not possible? Have these species lost their susceptibility to plasmodial parasitism?—or their taste for human blood? Have all rural homes in the South been made secure against insects?—and do their occupants remain indoors after dark so punctiliously that they are no longer accessible to mosquitoes? A brief review of these and other possible nullifying influences seems desirable (1) to

* Presented before the Georgia Public Health Association, June 10, 1947, and the American Society of Tropical Medicine and the National Malaria Society in Atlanta, Georgia, December 4, 1947.

assess the evidence for or against their causal participation in the current malaria regression, (2) to judge the extent, if any, to which these phenomena may be due to purposeful control efforts, and (3) whether it would be wiser, in view of the present low level of malaria incidence, to stop all organized attempts at further malaria prevention as unjustified expenditures, or to continue them with the hope and expectation that, within the foreseeable future, they will result in the total eradication of the disease.

Economic improvement in the South—The South shared in the nation's present wave of prosperity which started its upward swing (see Figure 2) at about the time malaria rates commenced their latest descent. In connection with this circumstance, it is pertinent to note that socio-economic progress was believed to be the prime determinant in the extinction of malaria in the Upper Mississippi Valley by various authorities,¹⁻⁵ though they disagreed as to the most probable means by which it was achieved. Malaria is more firmly entrenched by environmental conditions in the South than it was in the North, nevertheless it seems probable that economic improvement is the basis for various pressures to which it is now yielding. Those which may be presumed to exert antimalarial influence include better housing, more medical and public health services, more drainage for agricultural and suburban development, enlarged use of insecticides in homes, enhanced animal husbandry, and increased industrialization with its attendant shift in population residence from rural areas to or near metropolitan centers. Wartime and post-war shortages of materials and professional personnel have doubtless prevented the fullest elaboration of these forces against malaria.

Human susceptibility—Considering first the human factors which may have

been involved in the present recession, there appears to be little reason for assuming that it is due to an American loss of susceptibility to initial infection or relapse. Well over a half million American soldiers and sailors,⁸ including many from the South, acquired malaria overseas from 1942 to 1945, inclusive, evidencing no resistance to the numerous strains of plasmodia encountered. Some of the tertian infections imported subsequently are still relapsing after three years. Paretics and other recipients of induced malaria in this country appear to accept and react to blood- or mosquito-transmitted infections with old or new strains of parasites in recent years as their predecessors did before them, according to observers whose investigations involve the extensive use of this procedure.⁹⁻¹²

Antimalarial medication—It is difficult to assess correctly the role of medication in the malaria decline. Since the days of "Sappington's Anti-Fever Pills," residents of endemic areas in the United States have consumed huge quantities of ethical and proprietary antimalarials with the object of treating or preventing malaria. It seems logical to expect that drugs which reduce parasite densities in man should diminish his infectiousness to mosquitoes at the same time, but this effect has not always been sufficiently realized to be of significance in the prevention of malaria.

Thus, while the world thankfully accords memorable prominence in medical history to quinine for the relief it has given to countless millions suffering from malaria, it is now well known that the drug possesses no prophylactic properties, except the ability to effect the temporary suppression of symptoms, nor can it be depended upon to extinguish completely any type of malaria infection. Therefore, it is doubtful if quinine interferes perceptibly with the transmission of the disease. Certainly there appears to be no reason for be-

lieving that it contributed any more to the control of malaria in the South since 1935 than before that date.*

Quinacrine hydrochloride (atabrine) was introduced into general use in the South during the middle and latter years of the decade when the present malaria recession was just getting under way. Its early experimental application as a mass therapeutic and prophylactic among predominantly Negro populations with almost exclusively falciparum malaria was associated with encouraging reductions in spleen, parasite, morbidity and mortality rates.¹⁴⁻¹⁶ Later observations in Panama,¹⁷ led to the conclusions that atabrine was no more dependable than quinine for malaria control purposes when used in treating parasite positives discovered at monthly blood surveys. Critical tests^{18, 19} and general experience in malarious areas during World War II concurred in establishing that this drug, while not much more effective than quinine against vivax and quartan malaria, is virtually a specific against falciparum infection, its use in therapeutic or suppressive dosages resulting in a high percentage of non-relapsing cures of this and no other type of malaria. This unique characteristic plus the temporal association of atabrine and the recent malaria decline qualifies atabrine medication as one of the possible causes of the recession, without defining its actual importance.†

Population migration out of rural areas—Since 1935, there has been a notable migration from rural to urban surroundings throughout the United

States. This was most marked during the first half of the present decade due, presumably, to military induction and to the attractions of higher wages and better living conditions in and near the more populous centers where materials and equipment for Defense and War Industries Programs were being fabricated.

From 1917 to 1940, there was small but steadily increasing progress in the industrialization of the South as northern manufacturers shifted their factories to take advantage of more favorable labor conditions below the Mason-Dixon Line. From July, 1940 to May, 1944, the South received 24.4 per cent of the \$14,000,000,000 authorized by the War Production Board for manufacturing plants and equipment; this does not include the cost of plants whose post-war conversion to peacetime industry is doubtful.²⁰ During the same period, considerable numbers of Negroes travelled to the northern states to escape the effects of a waning cotton economy and with the hope of finding more productive and congenial surroundings.²¹

In many sections of the southeastern quadrant of this country, these events have resulted in transferring people *out* of rural areas where they might have had malaria and *into* urban situations where the chances of acquiring it were negligible. The total extent to which this phenomenon has taken place is not known at present, but some idea of its trend is conveyed by the upper curve in Figure 3, which indicates the progressive reduction in farm populations in the South Central and South Atlantic states from 1935 to 1945, inclusive. Thus it seems probable that a considerable depletion in rural population

* According to Norman Taylor, Director, Cinchona Products Institute, Inc. (personal communication), this country, prior to 1939, used roughly four million ounces of quinine each year, the annual variation being within 10 per cent of this figure. Its consumption "over a period of years" did not increase with the population. There is no way of determining the actual proportion used as an antimalarial in the South but, on the basis of available distribution data, it was estimated at the Institute that about two million ounces were used for that purpose.

† Information regarding the distribution and consumption of atabrine in this country could not be obtained from its principal manufacturer as the output of this product for the last six years has been controlled largely by the Army, Navy, and Public Health Service, and has been subject to use abroad as well as in the United States.

FIGURE 3—Estimated farm populations and numbers of all cattle in the South Atlantic and South Central United States, 1930-1946, inclusive.

has occurred. This may have assisted materially in malaria reduction in the last five or six years.

Anopheline susceptibility—Consideration must also be given to the possibility that changes in anopheline populations may have interfered with the transmission of malaria. Among such hypothetical factors, reduction in mosquito susceptibility to plasmodial parasitism due, perhaps, to environmental or cosmic influences would be of paramount significance if demonstrable. Such a phenomenon might be reasonably expected to manifest itself in insectary-reared as well as wild strains of mosquitoes. There is no published evidence to that effect with reference to the principal transmitting species in this country. Induced malaria for therapeutic and experimental purposes appears to have been transferred from

one person to another by means of mosquitoes with comparable degrees of regularity throughout and prior to the period under consideration.⁹⁻¹² While most of the naturally induced malaria has been transmitted with the Boyd strain of *A. quadrimaculatus*, established in 1932,²² other insectary stocks have been used and wild strains of this species have been brought into laboratories and their infectibility proved.^{12, 23, 24} Furthermore, it was shown in 1947 that native cases of falciparum and quartan malaria in South Carolinian Negroes, with or without symptoms, were readily infective to insectary-reared and wild-caught *Anopheles quadrimaculatus*, even though gametocyte densities were very low in some instances.¹³

Antilarval measures—Has the abundance of this transmitter diminished

sufficiently during the last twelve years to account for the malaria reduction observed? During this period, efforts of considerable magnitude have been made by federal, state, and local health agencies, and by private interests aimed at reducing anopheline densities, both on a community-wide basis and within homes. Entomological evidence of success as a result of these endeavors is limited; their probable effectiveness must be inferred largely from the nature and scope of their physical accomplishments.

The U. S. Army's continental experience with malaria during World War I was severe enough (see Figure 4) to require environmental control measures around southern cantonments. These activities had to be financed jointly from federal and local resources, thus directing attention to the fact that local governments were unable to bear the costs of malaria control operations which, as then conceived, were mainly antilarval.

Thus, during the depression years which followed, federal relief organizations (Civil Works Administration and Federal Emergency Relief Administration established in 1933, and the Works Progress Administration in 1935) were called upon to supply man power for malaria control purposes. They completed a tremendous amount of drainage in 16 southeastern states. The exact total is uncertain as existing reports of accomplishment^{4, 25} are not in agreement, but from them it appears probable that something in the neighborhood of 32,000 miles of "average-size" ditches were constructed draining 623,000 watered acres. Most of them were dug by hand labor—machine and dynamite excavation accounting for only a minor percentage—and a few hundred miles of the ditches were paved with concrete.

From the standpoint of good malaria control practice, these projects had serious faults. In the fulfillment of relief objectives, operations could be

FIGURE 4—Malaria admissions per thousand men per year for the U. S. Army in the Continental United States during World Wars I and II. Note the reduced military malaria experience in this country during the last World War.

MALARIA ADMISSIONS PER THOUSAND MEN PER YEAR FOR THE ARMY IN THE CONTINENTAL UNITED STATES. WORLD WAR I—WORLD WAR II.

carried out (1) where and only for as long as the numbers of locally unemployed were large enough so that crews could be manned for malaria control drainage as well as for other relief labor projects desired by the community, and (2) where locally provided materials and equipment were available for matching against federal funds. These conditions tended to concentrate malaria control drainage projects in the more populous and wealthy counties, not necessarily the more malarious ones. Justification for locating work units was frequently based on nothing more than lay testimony of past malariousness. Drainage construction was restricted to new works, which meant that existing drainage-ways could not be maintained or improved with relief labor nor could it be used to keep in serviceable condition the ditches which it dug originally. In many though not all instances, local governments have provided for the maintenance of the drainage facilities.

As the Defense Program gathered momentum in 1941, national unemployment declined and many of the WPA Malaria Control Drainage Projects were discontinued except in the neighborhood of military training camps. During 1942, these were taken over by the U. S. Public Health Service and, together with other environmental malaria control operations around areas of military or war industries significance, were continued during the war years as a coöperative works program of the federal and various state health services concerned. Their efforts were coördinated by the Office of Malaria Control in War Areas, headquartered in Atlanta, Ga.

During the period of maximal military training and industrial production, malaria control drainage, filling, and larviciding were accomplished by this organization around approximately 2,200 localities of military concern in 19 different states. Through 1945,

these activities included clearing and cleaning, incidental to larviciding, of 37,000 watered acres and 96,700,000 linear feet of ditches; 5,700,000 gallons of oil and 73,000 pounds of Paris green were used in larviciding 660,486 acres; approximately 10,900,000 linear feet of drainage ditch of varying cross-section were dug (90 per cent of them by hand labor, 5 per cent with dynamite, 3 per cent by heavy machinery, while the other 2 per cent were lined or tiled ditches); mechanical and hydraulic fill amounted to 315,000 cubic yards.

This program was a great improvement over the preceding one from the standpoint of malariologic principle. Maintenance operations could be undertaken as readily as new construction. Local contributions were required only when adjuncts to drainage works such as concrete ditch-lining or culverts, tile, dynamite, etc., were desired. Early in the development of the War Areas Program, the policy was adopted of basing operations on potential malariousness, i.e., presence of infectible species of anophelines, rather than on lay testimony of previous malariousness. Entomologic evaluations were made throughout the progress of the program to check operational accomplishments. These have been summarized in Figure 5 and show (1) that malaria-carrying types of mosquitoes were less numerous within the zones where mosquito control activities, exclusively antilarval until the calendar year 1945, were carried on than in adjacent unprotected areas, and (2) that anopheline abundance in uncontrolled areas was certainly no less; probably more, in 1946 than in 1942 when enumerative observations were commenced. Spleen and parasite surveys were also made for evaluative purposes but were not very meaningful because of their lack of sensitivity in the face of decreasing malaria prevalence. Community health education and information programs

point of public health insignificance the malaria prevalence which existed when construction was begun. It is interesting to note that, due to a combination of uncontrollable circumstances in the early spring of 1945, anophelism in the lower two-thirds of the Valley reached the highest level recorded in twelve years, but without evidence of an accompanying increase in malaria prevalence.⁷

This incomplete catalog of federally stimulated efforts at reducing anopheline production is impressive but the effect of these endeavors on malaria prevalence is hard to appraise. Their application extends over the period of malaria decline, a fact which should neither hastily be dismissed as fortuitous nor taken for granted to have causal significance. That malaria reduction occurred near many of these operation sites as a result of breeding place destruction and antilarval measures is indisputable, but that these areas were sufficiently numerous, extensive, or malariogenically important to produce a coalescent malaria depression throughout the South is hardly credible. Furthermore, malaria has diminished to a greater or lesser degree in areas beyond the influence of the TVA and untouched by WPA or MCWA. Thus, it is evident that other factors in addition to interference with anopheline production have been concerned in this phenomenon.

Measures against adult anophelines—In spite of active educational efforts, demonstration projects,²⁷⁻²⁹ and higher incomes, the amount and quality of domestic insect-proofing has increased significantly in only a few of the rural sections of the South where it would

have its greatest effect as a malaria reductive measure.^{30, 31} Doubtless, this is due to the excessively high ratio of insect-proofing construction and maintenance costs to the value of poorer type houses.^{32, 33}

On the other hand, the use of domestic insecticides has increased prodigiously during the period under consideration. Data concerning the actual amounts packaged and sold are difficult to obtain as these are viewed by dealers as competitive information; however, certain regional distributors (serving the southeastern states) and national manufacturers were willing to disclose production trends in terms of annual percentage increase. According to the estimates of the former, the distribution of these products, commencing with 1931, increased each year by amounts which varied with different concerns from 20 to 40 per cent until 1943, when output was crippled by lack of metal for containers and handsprayers. Compounded at the annual rate of 20 per cent, this would represent an overall increase of nearly 7½ times for this period.

One national producer wrote that the volume of his company's household insecticide distribution in the southeastern states increased 1,404 per cent from 1935 to 1945, but he believes that this was due to the energetic advertising of his concern and that competitive business did not advance to that extent. However, one of his principal competitors supplies the following indices expressing in terms of percentage relationships, based on business done in 1939, the amounts of domestic insecticides distributed by his dealers in 13 southeastern states (figure for 1939 being taken as 100 per cent).

| Year | Per cent | Year | Per cent | Year | Per cent | Year | Per cent |
|------|----------|------|----------|------|----------|------|----------|
| 1931 | 20 | 1935 | 52 | 1939 | 100 | 1943 | 160 |
| 1932 | 27 | 1936 | 64 | 1940 | 85 | 1944 | 139 |
| 1933 | 32 | 1937 | 75 | 1941 | 89 | 1945 | 140 |
| 1934 | 42 | 1938 | 79 | 1942 | 147 | 1946 | 56 |

This manufacturer is of the opinion that the sharp decrease in sales volume during 1946 was due to the large amount of "free" spraying which was done by local and federal government agencies during that year.

These indications, while remarkable, do not tell the whole story because numerous small operators commenced domestic insecticide production during this period, thus adding materially to the total made available to consumers. It is probably conservative to estimate that 10 to 20 times as much household insecticide was used in the southeast during the early war years as in 1931 to kill mosquitoes as well as other domestic insects.

In 1945, the Office of Malaria Control in War Areas embarked on its Extended Program of malaria control. This consisted of the application of residual DDT to the interior surfaces of homes and privies in counties where substantial mortality from malaria* had been reported during the period just before World War II. This was aimed at preventing the dissemination of malaria from home-coming veterans who had acquired infection overseas. From January 1, 1945, to September 27, 1947, nearly 3.2 million house-spraying applications were made in rural areas or small towns in 309 counties. The average number of sprayings per house varied from nearly two in 1945 to not quite one and one-half in 1947, when 875,534 different houses were treated.

Domestic insecticiding with residual chemicals such as DDT appears to be the most feasible single approach to malaria prevention now available in the South, considering the special problems of house construction, the distance be-

tween homes in rural sections, and the economy of the inhabitants. Most anopheline mosquitoes bite only at night and as more people are within their homes than elsewhere during the hours of darkness, it follows that measures which prevent mosquitoes from entering houses or which destroy the insects after they are inside are of transcendent importance in preventing malaria transmission. It is probable that the insecticidal applications, both ephemeral and residual, made within the home in the last 12 years have accomplished more than any other one measure to reduce malaria transmission in the South.

Anopheline deviation — Another circumstance which may have been of considerable assistance in reducing the domestic density of anophelines is the expansion of cattle raising in the southeastern states. The lower curve in Figure 3 shows the estimated cattle population in the South Atlantic and South Central states from 1930 to 1946. Cattle husbandry has increased in the South as cotton cultivation has receded in importance and as rural labor has migrated out of the region. Longer grazing seasons than are available elsewhere in the country, less labor requirements, accessibility to eastern markets, and better protective techniques now available against cattle diseases spread by biting arthropods are said to be factors contributing to this development. The presence of more cattle is believed to be important, malariologically, because *A. quadrimaculatus* has a strong preference for cattle blood.³⁴ As these mosquitoes emerge from their breeding places and seek blood meals, they are less likely to enter human habitations in large numbers if they can satisfy their appetites more conveniently from cattle in the fields or in stables close to houses.

The trends of the two graphs in Figure 3 indicate that the decrease in

* In the calendar year 1946, counties were approved for Extended Program operation if the average annual malaria mortality rate during 1938 to 1942, inclusive, was 10 or more per 100,000 population. In 1947, the base was broadened to include rates down to 5 per 100,000. Counties with evidence of current malaria morbidity were included both years.

the farm population of the South occurred while the cattle population was on the increase. This suggests that the antimalarial influence of these two circumstances may have been compounded by their contemporaneous development.

DISCUSSION AND SUMMARY

Until medical and public health practices in the reporting of malaria cases and deaths are improved to the point of being more dependable measures of the actual morbidity and mortality due to this disease, certain reservations must be entertained concerning its real status and shifts in prevalence. It does appear to be diminishing, however, and on the basis of the foregoing, the following tentative deductions seem to be justified. Certain of these, derived from information collected over broad regional expanses, deserve more searching and precise investigation in restricted study areas to determine the nature and extent of their local impact on the incidence of malaria.

It appears that there has been no essential deterioration in the potentialities of the parasite-host-vector system of malaria transmission in the United States during the last twelve years. The infectivity of the various species of *Plasmodium* capable of parasitizing man and transmitting mosquito remains unimpaired. It seems more likely, therefore, that the malaria recession can be explained in terms of quantitative rather than qualitative changes.

The widespread efforts at areal reduction of anophelism in the South by antilarval measures have depressed and possibly extinguished malaria endemicity in certain localities, but it is doubtful that these programs were primarily responsible for the regional decrease. The reduction of *domestic* densities of anophelines by the use of insecticides, as a result of deviation by cattle, and to a lesser extent by insect-proofing of houses is held to be a more important

and uniformly extensive causal factor.

Other circumstances contributing to the general decline are (1) population movements from rural areas in the South where malaria could be acquired, to urban centers in the South or to other parts of the country where malaria does not occur, and (2) improved anti-malaria medication.

Economic advance has undoubtedly stimulated the development of most of these factors. A depression might be expected to send people out of the cities back to the country where unimproved housing would quickly deteriorate in the absence of maintenance. Money would not be spent for household insecticides and the most effective anti-malarials. Under such conditions, malaria could again become a public health hazard of great prominence.

If malaria can be eradicated in this country and its reintroduction prevented or controlled—and this possibility is viewed as reasonable—^{8, 35, 40} economic depressions could have no malariogenic effect. Malaria prevalence and transmission have reached new lows. Control techniques are more effective today than ever before, though doubtless their efficiency can be still further improved. These considerations constitute compelling motives for taking advantage of our present strong position. They offer a challenge to national, state, and local health agencies to combine in effecting the complete annihilation of the "world's greatest scourge"³⁸ in the United States.

Some Labor Union Enterprises in Public Health Economics

B. A. KOGAN, M.D., DR.P.H.

*Director of Maternal and Child Health, Department of Public Health,
Oakland, Calif.*

PUBLIC health is medical sociology. The broad scope and numerous tools of its practice necessitate specialization. Recently, and belatedly, an old specialty in the field has been newly defined as public health economics. Its rudiments, though inherent in social organization, have until recently been inadequately studied.

Mutual sickness and death benefits were not unknown among the ancient Hebrews, Greeks, and Romans. Many medieval guilds, despite primary religious or economic purposes, included provisions for such benefits in their charters. These primitive efforts were plagued with insolvency. In 1793, however, England saw the first legal restrictions designed to create financial security in friendly societies. More than a century of experience followed during which considerable opposition to increasing government interference developed; the National Insurance Act of 1911, an expression of majority rule, temporarily settled the argument. In this country the course of labor has been altered by basic differences in public health economic history; not the least important of these was the opposition of Samuel Gompers to any form of national health insurance. His social philosophy, in this respect, is essentially comparable to that of Senator Taft. By the mid-thirties, several great American unions were paying old age, death, disability, sick, and other benefits which had de-

veloped fortuitously and were frequently inadequate.

Space does not permit complete discussion of historical factors. The purpose here is to consider some recent efforts made by certain American labor organizations in redistributing the cost and thereby sharing the economic risk of sickness.

The First UAW Medical Research Institute—In June, 1937, an undue incidence of lead poisoning among auto workers, a desire to provide medical care for strikers, and interest in promoting both an industrial health education program and an industrial disease law led the UAW-CIO to open a Medical Research Institute. The purpose was research in the field of occupational disease. Collected data, obtained through worker and plant examinations, were to be used in formulating demands for better working conditions from management and government. Members, suspected of having an occupational disease, were to be referred to the Institute by shop stewards and union committeemen. Therapy and legal medicine were, initially, specifically omitted from the program; the latter limitation was, however, obviated by a new industrial disease law. Union physicians helped members to meet the medicolegal talent of the companies but their major interest lay in the concept that union support of an industrial disease law prompted installation of pro-

tective devices which would reduce industrial disease and injury. Patients requiring treatment were given the names of two physicians from a list supplied by the Wayne County Medical Society.

In 1938, in the midst of a growing program, during which thousands of men were examined and industrial disease and accidents decreased spectacularly, the Institute was discontinued. Unstable financing and lack of intra-union harmony were the causes. Specifically: (1) the financial responsibility for the Institute could not be settled; (2) the Institute had opened just after the union had increased membership from 25,000 to 300,000 and had collected \$327,000 in initiation fees. The layoffs, strikes, and lockouts of 1937 and 1938 decreased collectable union dues despite an increasing membership; (3) the union tended to concentrate available moneys on the Ford organizing drive; (4) the UAW split into UAW-CIO and UAW-AFL factions which resulted in the tying-up, by court order, of all Institute equipment. It took almost two years for the courts to decide which faction had title to the property.

The Second Health Institute of the UAW-CIO—In 1943, in accordance with previous convention resolutions, the UAW-CIO Health Institute was re-opened and is now supported by (a) per capita assessments of over 350,000 members, (b) community chest donations, and (c) international subsidies. In its present quarters (the former home of the Edsel Ford family) are offered medical diagnosis by general practitioners and specialists, health education, and personal services. Many interested agencies, such as universities and the Detroit Health Department, are coordinated in the program.

The diagnosticians, using union technical services, such as routine blood and urine examinations, E.K.G., B.M.R., and x-ray are not only able to cut the

expense of diagnosis for a patient but also provide the advantage of earlier diagnosis. Patients are referred elsewhere for treatment; the Wayne County Medical Society assists in this. The most common diagnosis is psychoneurosis; such members are referred to the Personal Service (social case work) division for assistance. Between July, 1946, and June, 1947, only 12.6 per cent of patient visits were related to industrial disease or injury.

The Personal Service Department is occupied with the multiple ramifications of social case work. Vocational rehabilitation, psychiatric referrals, assistance in mental hygiene, cooperation with other referring or assisting agencies are but a few of the major duties of this staff of two trained social workers.

A remarkable health education program provides well attended classes taught by authorities. Health and Safety classes train local leaders to become foci of information for others. They know their machines; such education betters their bargaining position for healthful working conditions. Industrial Psychology is taught to improve intraunion and labor-management relationships. Consumer Health and Physical Education classes ("charm classes") attract female members and wives of male members. A Health and Human Relations course deals with emotional, sociological, and economic problems of women. Swimming and Health Education and Dancing and Health Education designate classes combining athletic activity with health lectures. This department is also responsible for exhibits, press releases, a monthly health pamphlet, mat service, and radio programs.

Member utilization of these services has increased tremendously in the past two years. It is idle to question the apparent values inherent in this public health economic enterprise. Despite obvious limitations (such as the absence

of a treatment program), it today surely justifies its existence. The permanence of the Institute must, however, be considered in the light of UAW-CIO support of a federal health bill, notorious intraunion disputes, and both labor and management threats to employment which inexorably curtail financial support of such ventures. The union has planned a hospital; but strikes cost money, and so do hospitals.

The Union Health Center of the International Ladies' Garment Workers Union—One consequence of a strike in 1910 was the selection of a Joint Board of Sanitary Control to study "sweat shops." The shocking conditions discovered by this group as well as by the U. S. Public Health Service resulted, in 1913, in the establishment of the Union Health Center. It flourished at first but, in the decade following 1922, intraunion disputes (culminating in the defeat of the communists), a catastrophic strike (1926) and the depression, all combined to jeopardize the Center. It was maintained largely because of the self-sacrifice of the idealistic personnel.

Weathering this adversity, the I.L.G. W.U. Health Center has, since the presidency of Dubinsky, grown enormously. A largely female (85 per cent) membership, seasonally employed and less demanding than men regarding wages, is appreciative of a convenient, sympathetic source of competent medical care, most of the cost of which is met by an employer payroll tax. Those few affiliates without prepayment medical services pay but \$1 per service.

This ambulatory clinic offers diagnostic and treatment services suited to the studied specific needs of the membership. In addition, it administers the medical aspects of the various local sickness insurance programs. There were, in 1946, nineteen different sick benefit and eight hospitalization plans; diverse cash benefits for surgery, maternity, convalescence, tuberculosis, and

eyeglasses were offered by a varying number of locals. Active health education, worker rehabilitation, and social work programs are in force. Despite the greatly expanded clinic space and services, there still remains the problem of meeting the ever growing utilization of the membership.

The reasons for this record are apparent. Aside from the advantages to the membership, one must point to the brilliant, often idealistic administration. Pure altruism cannot, however, be an objective criterion in evaluating the permanency of a public health economic enterprise. Moreover, the Dubinsky era of harmony is a personal victory, not reflective of the entire union history; the inevitable termination of his presidency might well be accompanied by familiar destructive discord. The comparatively attenuated basic problem of this union is collective bargaining for better wages, hours, and working conditions; the Center experience may well be used in promoting this function. However, the success of a union enterprise in public health economics can be at the mercy of all the vagaries of labor economics and politics. Social ventures can be a cohesive intraunion force; their stability is weakened in so far as they are a subsidiary, rather than a primary, union function. Finally one must question the stability of an employer payroll tax (gained during a business boom) in an economic depression.

The Dental Clinic of the Chicago Amalgamated Clothing Workers—The then Dean of the Northwestern University Dental School, in an interview in 1928, regarding the newly opened, well equipped and staffed ACW dental clinic, was quoted as follows in a union publication: "The Amalgamated Dental Clinic will serve not only the 25,000 members of the union, it will serve 100,000 because it will take care of the families of these members."

These high hopes failed to materialize.

Examination of overhead (salaries, dental equipment, laundry, magazines) and income (primarily collected from dental fees, sales of tooth paste, toothbrushes and dental floss) reveals that, from inception until mid-1945, the clinic operated under persistent financial deficits. Since competent service at reasonable fees, and not profit, is the primary purpose of the clinic, a strict financial judgment may seem unjust. However, operating losses and gains do provide a concept of the service utilization. By mid-1945 a total of 3,924 patients had been seen, an average of 230 yearly. Less than about 1 per cent of the eligible members and about 0.25 per cent of all eligibles had availed themselves of the service. From October, 1943, to July, 1945 (twenty months of acute dentist shortages), the salaried dentist saw 98 new patients, an average of 4.9 per cent monthly. The employed personnel had dwindled, by mid-1945, to an unassisted dentist; the laboratory was unused.

This public health economic enterprise has failed because (1) the union leadership has not adequately educated the membership regarding the service; (2) the hours and location of the centrally located clinic are inconvenient for the decentralized membership; (3) the fees are not comparably low enough to warrant sacrifice of the individual choice of a dentist; (4) adjustments in dental practice are unavoidably frequent; foci of dissatisfaction in general dental practice are usually lost in a large community; in union practice one patient's dissatisfaction may be spread to an entire local.

Why is the clinic maintained? It is a symbol of intraunion cohesion. In a letter dated July 18, 1945, the manager of the Chicago ACW wrote this writer:

"Our organization is not a business organization, nor is it looking for profit. We have other departments that are not financially sustaining themselves, as our cultural groups,

concerts, and educational work. All these departments are not profitable departments, but are essential . . . we feel that if we can give them the best services for a reasonable cost to whatever members are willing to avail themselves of it, we are protecting and servicing at least that many people with the knowledge that our organizational intentions are to give them more service."

The UAW-CIO and the Blue Cross Plan—The early success of the Michigan Blue Cross Plan is largely due to the UAW-CIO. Although the insurance agreement is between employer and insurance company, union-employer agreements have resulted in the enrollment of over 350,000 members from the Chrysler, General Motors, Packard Motors, Continental Motors, and Briggs companies alone. It is estimated that over 50 per cent of the total Michigan Blue Cross enrollment is comprised of about 225 UAW-CIO groups. The Group Hospitalization Report of February, 1941, by the UAW-CIO Chrysler Committee, in selecting the Blue Cross over the Aetna contract, illustrates the union capacity to override the express recommendation of the employer. The Fruehauf Trailer Company even experienced a strike because of its reluctance to discuss insurance plans with the union.

This vast free advertising agency is recognized by the Blue Cross directors. Five union men, employed by the insurance company, act as trusted advisers for the assured. Their position is analogous to that of union shop committeemen who are paid by industry but work for the union for the common good. The functions of the union member committee of the Blue Cross Plan are: (1) to assist in claim adjustments; (2) to act as an educational buffer between members and insurance company; (3) to present union grievances to the insurance executives; (4) to promote Blue Cross enrollment at local meetings.

These arrangements augment the familiar benefits of the Blue Cross con-

like histologic lesions by sensitization with sulfonilamide. Especially is this true, considered in the light of the Army Air Force experience, where frequent reactions to the sulfonilamides were caused by repeated administration of the drug when given in prophylactic dosage to the Army Air Force personnel. Toxic reactions are few if the drug is withdrawn when the early symptoms of hypersensitivity appear. Severe reactions occur if the drug is administered repeatedly to sensitized individuals. Therefore, in every epidemic the streptococcus should be tested *in vitro* to find out if the epidemic strain is definitely inhibited by low concentrations of the drug. It is of more importance that the drug should be withheld from all persons who are sensitive to sulfonilamide, and that all persons receiving the drug be readily available for frequent examinations by the physician.

Biologic prophylaxis with the use of sera and vaccines has so far proved unsatisfactory. Immunity is type-specific, and polyvalent vaccines are required. The real danger in inoculation of human beings by these organisms is the production of streptococcal tissue hypersensitivity, which may increase the possibility of causing post-streptococcal complications such as rheumatic fever, if and when suppurative streptococcal invasion of the throat occurs.

Antibiotic prophylaxis is expensive and, as yet, impractical. Penicillin therapy at the time of the invasion of the tissues of the throat shortens the illness and has proved to be the best preventive of the post-streptococcal complications and of the reactivation of quiescent rheumatic fever.

If a substance which acts like the salicylates, in a very effective way, can be found, then the sensitizing reaction will be blocked. The hope of investi-

gators working at the present time, is to find a substance which will prevent the antigen of the streptococcus from sensitizing the host, and thus block or prevent the post-streptococcal state.

SUMMARY

1. The epidemiology of rheumatic fever is the epidemiology of the Group A hemolytic streptococcus.

2. Respiratory disease caused by the hemolytic streptococcus predisposes to the post-streptococcal non-suppurative complications.

3. Rheumatic fever is a contact disease, and not primarily due to an inherited susceptibility to the disease.

4. The public health measures for the control of rheumatic fever are similar to those instituted so successfully in the control of tuberculosis.

5. Isolation, control of carriers, air sterilization, and possibly chemoprophylaxis are measures necessary for the prevention of epidemics.

6. The chief problem is the protection against, or the elimination of, infection by streptococci from the whole population.

7. A blocking agent, to prevent the development of the post-streptococcal syndrome, i.e., rheumatic fever, is a logical attack upon the problem.

8. The solution of these problems is the first step in the prevention of rheumatic heart disease, and perhaps in the prevention of the wide-spread vascular diseases, as well.

General Reactions of Mothers and Nurses to Rooming-in

Observations Based on Experience in a Four Bed Rooming-in Unit in the Grace-New Haven Community Hospital (University Service) *

EDITH B. JACKSON, M.D.

Associate Clinical Professor of Pediatrics (Psychiatry) Yale University School of Medicine; Attending Pediatrician, University Service of Grace-New Haven Community Hospital, New Haven, Conn.

ROOMING-IN is the term used for the hospital arrangement whereby a mother may have her baby in a crib beside her bed. This paper summarizes the general reactions of mothers and nurses to rooming-in as carried on during the past 11 months on the maternity ward of the Grace-New Haven Hospital in the so-called Rooming-in Unit. The Unit is housed in the maternity ward solarium which has been partitioned off into a four bed, semi-private ward with attached four cubicle nursery and doctors' and nurses' office. The baby's crib is usually by the mother's bedside but may be moved to the nursery at the end of the room as occasion arises. The upper part of each partition is glass with draw curtains, so that there may be visibility or seclusion as desired. The partitions stop three feet short of the ceiling for ventilation purposes. The ceiling and side walls of the nursery are treated with acoustic-celotex to reduce the intensity of sounds and noises. The room is cheery and attractive. The Rooming-in Unit is thus a comfortable division of hospital space wherein four mothers and their new-born babies may be cared for together under unified nursing and medical supervision, and where

each mother may observe her baby to her heart's content and learn to take care of him before she leaves the hospital.

As hospitalization for maternity cases has increased during the last 25 years, many mothers have felt the lack of opportunity to get acquainted with their babies during the lying-in period. They have subsequently admitted feeling panicky and helpless in dealing with the baby immediately after coming home from the hospital. During this same period, some physicians who have had the opportunity to study feeding problems and other behavior disturbances of infants and young children, together with the neuro-psychiatric disturbances of adults, have expressed the opinion that the separate care of maternity and new-born patients in the hospital and the extension of the hospital's rigid schedule into the home has offered a favorable medium for the growth of unnecessary conflict between mother and child. Furthermore, mothers from all sections of the country who have wanted to nurse their babies as a natural maternal process have felt thwarted by the disinterested attitude of the hospital medical and nursing staffs in supporting their wish to nurse. They have felt both puzzled and hurt by their failure to provide what they had reason to ex-

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

sider was the best food for their infants. Some physicians (pediatricians, psychiatrists, and obstetricians) listening to such comments and complaints from intelligent parents, have gained a conviction that the hospital's institutional need for regularity and regime has blocked a recognition of the mutual needs of mothers and new-born babies within the hospital.

Since the major part of the education of physicians and nurses is in hospitals, and since approximately 80 per cent of the babies born throughout the United States and 90 per cent of the city born babies are at present delivered in hospitals,¹ hospital practices have very far-reaching effects, and also very profound effects, for they bear the stamp of the acme of medical authority. Physicians, nurses, and parents educated in the hospital to a firm belief, both in the nursery segregation of new-born infants and in strict routine and regularity as a correct procedure for infant care, have had little reason to question either until practical experience or further education or both has taught and convinced them otherwise. There are now throughout the country parents, physicians, and nurses who singly or in groups are expressing other convictions.²⁻⁷ Good hospitals, they are saying, have certain advantages over homes for safety in maternal and new-born care; good homes have certain advantages over hospitals in naturalness and comfort. Protection from infection and protection from discomfort may be equally essential for the baby's happy, healthy development and for the mother's ability to give adequate care to her child. Cannot the advantages of safety and home-like comfort be combined in the hospital for the welfare of normal healthy mothers and infants, and for the more realistic education of parents, physicians, and nurses in the interrelationship of maternal and infant needs?

The Rooming-in Unit on the Univer-

sity Service of the Grace-New Haven Community Hospital is the joint co-operative attempt of the Department of Pediatrics and the Department of Obstetrics and Gynecology of the Yale University School of Medicine, of the Yale School of Nursing, and of the Hospital Administration to answer that question.

REACTIONS OF MOTHERS

In discussing the reactions of mothers we will consider first the reactions of prospective mothers to the idea of rooming-in. During the first 3 months of our work the existence of the Unit was not generally known. We could, therefore, question the expectant mothers in Prenatal Clinic with reasonable assurance of a spontaneous response from them, unbiased by previous hearsay or consideration. Our initial phrasing of the question was as follows:

In our experience we have found that some women think that they might prefer to have the baby in the room with them in the hospital. Other women would rather have their babies in the nursery and brought to them at regular feeding hours. Which would you prefer?

This question was asked only of the mothers who in a preliminary or screening interview had signified their wish to breast feed, since we were studying rooming-in with special reference to the type of woman who wanted help and encouragement from the hospital in undertaking to breast feed her baby. There were many immediate smiling responses to the suggested idea of having the baby close to the mother's bed; there were some incredulous, hesitant, dubious responses, and a few immediate negative responses. Table 1 figures from the first 8 months indicate, however, that of the mothers who looked forward to nursing the baby, more favored the idea of rooming-in than disapproved of it.

As a further check on the reaction of expectant mothers to the idea of room-

TABLE 1

| Expectant mothers offered the possibility of rooming-in arrangement..... | 235 |
| Wanting rooming-in..... | 175 |
| Did not want rooming-in..... | 60 |

ing-in during the last 3 months (from July 1 to September 30, 1947) every mother interviewed in the Prenatal Clinic by a member of the Rooming-in staff has been asked whether she would like to have her baby beside her bed if it were possible. Table 2 figures indicate that more than half of the expectant mothers (whether they wanted to breast feed or bottle feed their babies) are positively in favor of the idea, that a quarter of the mothers are definitely opposed, and the remaining one-fifth of the total group are indifferent.

TABLE 2

| <i>Attitude of Expectant Mother</i> | <i>Number</i> | <i>Per cent</i> |
|-------------------------------------|---------------|-----------------|
| Favorable | 184 | 55.0 |
| Unfavorable | 88 | 26.5 |
| Indifferent | 59 | 18.5 |
| | <hr/> 331 | <hr/> 100.0 |

This test of attitude toward rooming-in of all expectant mothers in the Prenatal Clinic was undertaken merely as a poll of opinion because of the increase in the number of spontaneous requests for rooming-in both from clinic and private patients. However, mothers continue to be selected on the original basis of (1) wanting to nurse; (2) wanting rooming-in; and (3) relative normality. Parity, age, race, economic or social status have not, *per se*, been determinants in selection; in these respects selection has been representative. The weighting of the selection in terms of the expectant mother's wish to nurse her baby has probably brought to rooming-in a relatively high proportion of well educated parents. In this connection it is a noteworthy fact that married nurses and wives of graduate students, of medical students, and of medical staff, have

been eager applicants for rooming-in and enthusiastic participants.

The first indications of satisfaction on the part of both mothers and nurses to rooming-in experience appeared promptly. The first group of student nurses assigned to the Rooming-in Unit made a special point of expressing their viewpoint in the following way at the end of their two week assignment:

"We know the mothers like rooming-in. We thought you would like to know the nurses like it, too, and when we have babies this is the way we would like to have them." The spokesman of this group married a few weeks later. She documented the sincerity of her response by applying for rooming-in shortly after she knew she was pregnant.

Some might comment that the first mothers to be cared for in the Rooming-in Unit would of course be pleased and satisfied; they wanted to come, in the first place, and the care and the attention would be particularly attentive under the stimulus of the newness of the venture. However, the enthusiastic response of the mothers has continued month after month. After all, for each successive group of mothers and each successive group of student nurses in the Unit there is the same stimulus of a new and vital experience. During the first 3 months most of the mothers wrote comments in notebooks that were provided for the record of their care of the baby. These comments were all on the appreciative side. We had every reason to believe in their sincerity, since very often practical suggestions were added. For instance, one of the first primiparous mothers called our attention to the fact that it might be better to assume that the baby should spend the first couple of nights in the little nursery at the end of the Unit, and not put the burden of decision on the mother. No mother, she said, would want anybody to think she did not want her baby, even though at the moment she wanted undisturbed

quiet most of all. Other mothers made other suggestions. It was evident that they enjoyed participation in an undertaking that was trying to make the mutual adjustment of mother and new-born a happy experience, for themselves and for their successors.

The same reasons for liking rooming-in appeared over and over again in the comments from different mothers, whether primipara or multipara. They liked to watch the baby, his facial expression, his smiles, his movements. They liked to hear his baby sounds. They did not worry what was happening to him as all multiparous mothers said they did when their former babies were in the ward nursery. They felt secure in having the same nurse take care of the baby who was taking care of them. They liked being able to ask either nurse or doctor questions as soon as questions arose. They learned much in the care of the baby by watching the nurse during the first few days, and gained assurance in taking care of the baby themselves under supervision during the last few days of the hospital period. For the most part, they liked the *ad lib* schedule, because they could observe the easy contentment of the baby. They greatly enjoyed the father's visits, and his participation in holding and learning to care for the baby.

The following appreciative comment on rooming-in, recently received from a mother with her first baby, is typical.

What do I think of Rooming-in? I think it is wonderful. There are a great many observations I could make—all of them complimentary. However, in that case this would become a thesis rather than merely a "list of comments," so I shall simply mention the two most important factors in my impression of this experiment.

My baby girl, Diane Margaret, and I will be going home tomorrow, and I know that if I had not been given the privilege of being in Rooming-in, I would be a nervous wreck tonight. I have often heard the adage that a new mother invariably cries the night before she goes home from the hospital. Well, I can

easily see why. Even though she has read literature on baby care and perhaps attended Mothers' Classes, still she has had no experience in caring for a real live baby. Here in Rooming-in, we new mothers learn first by watching the nurses care for our babies, and then we augment that knowledge with actual experience. Also, we are given answers to all the many important and perhaps some trivial questions that come into our minds as we watch that wonderful little son or daughter.

Our course in Mothers' Classes gave us a great many helpful hints on breast feeding, but in Rooming-in, through the untiring efforts of the nurses and doctors in charge, a mother's desire to nurse her baby finds fulfillment. This is the most important reason why I hope there will be many Rooming-in Units in the new hospital. There are many girls today who sincerely want to breast feed their babies, but they are never given the right start in the hospital, and they find themselves going home with a bottle-fed baby. This situation is a disgrace.

Another great advantage of Rooming-in is that the previously neglected father, who could only see his baby through a glass window, now is given his rightful privilege. He now can watch his baby, hold her, learn to care for her. Consequently, when mother and baby come home, he does not feel afraid or self-conscious, and can be a real help and comfort.

The multiparous mothers, without exception, expressed preference for the rooming-in experience over their previous hospital experience, and stated that they got as much if not more rest in rooming-in as they had had previously; in any event, they said, they felt stronger and more rested at the end of their hospital stay and much more ready to undertake the care of the baby at home. Furthermore, they expressed appreciation for the companionship with other mothers which the Unit afforded. They learned much by observing the other mothers with their babies and exchanging experiences. They became used to the idea that each baby was quite different from every other baby, and that each baby differed in reactions from day to day. They felt they were going home with a baby they really knew, and not with a perfect stranger. Many commented after they had gone

each nurse is able to take care of several mothers and babies throughout the lying-in period and conversely that the mothers have the same set of nurses caring for them throughout their hospital stay. This has been a satisfactory and instructive arrangement for both mothers and nurses. In the first 10 months of operation of the Unit there have been approximately 60 student nurses who have had this experience. Each student has written an evaluation of her obstetrical experience contrasting the experience in the Rooming-in Unit with that on the usual obstetrical ward and nursery service. The obstetrical supervisor⁸ has stated:

Without exception every single student who has been assigned to the Rooming-in Unit has been most enthusiastic about her experience there. Their comments were all in favor of the arrangement. The students say over and over again that this is the first time in their nursing education experience that they have been able to give what they consider ideal care to a patient. I am convinced that this bit of experience, although at the present only 2 weeks in length, is of unexcelled value to the student. She is able to observe every single thing that happens to the mother and the baby and the mother and baby together. She has an opportunity to teach the parents about their new baby. She has an opportunity to explain to them or to answer for them many of the questions that come up in this new relationship. . . . I believe that the nurse giving this care will herself be better prepared both as nurse and as potential mother.

One student writes in contrasting her maternity ward and new-born nursery experience with her rooming-in experience: "It was a sort of race with time that left no individuality for anyone. There wasn't time to wait and see if the baby had taken the breast nor was there time to stop and encourage the mother with the poor nurser, but rather some impatience with the mother who wanted to finish combing her hair or fixing her face at 6:00 a.m. rather than taking the baby. Rooming-in was a great change from the aforementioned. Although we were kept busy, we were not rushed, and there was plenty to do. Having the mother with the baby seemed to make the mother more considerate of the nurse's time. She didn't ask for things to be

done when she could see that the nurse was busy with another mother and baby."

Another writes: "There is a relaxed, peaceful attitude about the Unit which runs without the everlasting clock-control that is found in larger units and especially in the nursery. I did not like working in the nursery or on the ward. In the nursery I felt as though I were running a machine which had to produce freshly diapered babies with a heated formula every 4 hours, and I did not like it on the ward because I felt intensely rushed with beds, baths, meals, and routine postpartum care."

The Visiting Nurse Association of New Haven is represented on the Rooming-in Committee. A cordial working relationship is maintained between the Rooming-in staff pediatricians and the visiting nurses who visit in the homes of rooming-in families through exchange of telephonic reports. As previously indicated, some of the visiting nurses have reported finding rooming-in mothers more independent than other mothers just home from the hospital and more quick to dispense with their practical help. Some of the visiting nurses have found, on the other hand, more time being claimed by rooming-in mothers who want to talk out with the nurse a somewhat complicated family or economic problem in relation to the baby's welfare. Reports on the babies have been generally favorable.

CONCLUSIONS

Procedures in the Rooming-in Unit have met with generally favorable response from both mothers and nurses (and also from staff physicians, fathers, and infants). It has proved to be a helpful educational experience for everyone involved. Multiparous mothers prefer it to the usual hospital procedure because of the help it offers them in getting a good start with the baby, and they therefore recommend it for mothers of first babies. It is too early to evaluate any long range effects. Rooming-in is not applicable to all mothers, and

polio epidemic when it strikes with full force at the heart of a community. For the full impact of an epidemic constitutes a major catastrophe within the stricken area, and an official agency can no more prepare for such an emergency than it can prepare for hurricane, earthquake or flood.

When polio strikes and your public health agency requests assistance, The National Foundation for Infantile Paralysis stands by with the resources of an entire nation at the disposal of the public health officer.

A community that has never experienced an epidemic of infantile paralysis cannot appreciate the resources, local, state, and national, that may contribute to the solution of its emergency situation. The National Foundation has been in the thick of the fight against polio for the past 10 years. The knowledge gained from intensive work in the field in every major epidemic the nation has experienced in the past decade is available to every community.

A polio epidemic calls for the broadest kind of action, based on preparation for such an eventuality in any part of the country. There is no time for governmental red tape, no time for trial and error, no time to train and instruct key personnel. There is time only for a quick shifting of equipment and trained personnel to the epidemic area. Our defense against this disease must be a fluid defense.

Any deficiencies become evident at the very outset of an epidemic. Faced with the necessity of providing adequate resources on short notice, local defenses soon break down under their understandable but, nevertheless, very real limitations. Only the combined efforts of both official and voluntary agencies working hand in hand, and with the financial support of the entire American nation, can be considered a maximum attempt to meet the emergency needs when polio strikes.

There are those who have severely criticised voluntary health agencies in general, and The National Foundation for Infantile Paralysis in particular, for alleged opposition to official health organizations. On the contrary, it is a matter of public record that wherever the National Foundation has contributed its services to the local picture—and the occasions are as numerous as the sporadic flare-ups of polio throughout the nation—it has worked with, and under, the direction of regularly constituted state, federal, and local health departments. Every one of its 2,735 county chapters is prepared to cooperate in every way with public health authorities in providing funds, in recruiting doctors, nurses, and physical therapists, in supplying trained Polio Emergency Volunteers and in securing every type of equipment from respirators and hot pack machines to hospital bedding and wool packs.

Its services know no barriers of state lines as it attempts to fulfil its pledge that no victim of infantile paralysis shall go without the best available care and treatment. Whereas polio is just a small segment of the function of the public health agency, the National Foundation is devoting full time to the conquest of this particular disease. Its services to public agencies do not terminate when the fury of the epidemic has been reduced to normalcy. Rather, with the lessons learned from years of firsthand study, the National Foundation has set about to aid official organizations in the correction of inadequacies that have become evident under the pressure of emergency.

Probably the most serious flaw in the public health program has been the scarcity of qualified workers to carry out the exacting tasks for which these agencies are responsible. Programs of public health demand interested and competent workers, experts in their field who are prepared to put into practice

new methods, new techniques and new standards. Personnel of this type can be obtained only by making special training available to qualified candidates, by financing postgraduate study in public health and by offering scholarships to promising students who are eager to make public health work a career.

The need for capable physicians and nurses, for sanitary engineers, bacteriologists, epidemiologists, statisticians, public health educators, and technicians is a need which has seriously limited the operation of official agencies. Through a series of direct grants to the U. S. Public Health Service and professional organizations, the National Foundation is financing the development of personnel to fill these essential positions. Fully realizing that the conquest of poliomyelitis hinges upon the intensity of the fight against all diseases, we are today strengthening the position of officially constituted organizations by contributing thousands of dollars to the training of public health workers. Let me tell you some of the things that are being done in this respect.

Early in 1946 there existed 1,200 vacancies for physicians and engineers in state and local health departments throughout the country. In a move to encourage widespread interest in public health on the part of physicians and engineers returning from military service, the U. S. Public Health Service applied to the National Foundation for funds to be used in the public health training of personnel recruited to fill these positions. The application was approved in July of last year and a grant of \$228,400 made to provide fellowships for qualified candidates. Up to September 30 of this year 35 awards have been made to sanitary engineers and 18 to public health physicians. Additional applications are under consideration. We feel that the presence in health departments of well trained health officers

and sanitary engineers assures us of maximum efficiency in our efforts to control poliomyelitis. And our support of official agencies does not stop here.

Health education through the facilities of the U. S. Public Health Service has long been hindered by the lack of trained personnel. The well trained health educator, working as a permanent member on the staff of the local health unit, has proved to be of invaluable aid in establishing an overall health program by coördinating the resources of both official and public health agencies within the community. The importance of the rôle played by the health educator has been increasingly recognized by local health officers, many of whom have budgeted funds for the employment of such personnel. But again we face the handicap of an acute shortage of qualified individuals who have a knowledge of both public health and education. To alleviate this situation The National Foundation for Infantile Paralysis has made, since 1944, direct grants to the U. S. Public Health Service totalling \$160,000 to be used for fellowships in public health education. With this support, a total of 58 awards have been made, and many more are needed to meet requirements of expanding health education activities.

The personnel shortage has also been felt severely in public health agencies with regard to orthopedic programs. Supervisory nurses with qualifications in both physical therapy and public health nursing have been most difficult to obtain. The preparation of individuals to fill supervisory posts entails great expense for the agency and for the nurse. In addition, the paucity of teachers of orthopedic nursing has severely limited the development of workers in this field. Only by offering real encouragement to nurses to qualify as directors and instructors of orthopedic nursing courses can we meet the demands of the future.

The National Foundation for Infan-

tile Paralysis is particularly interested in this phase of public health work, for it relies heavily upon the skill of experienced orthopedic nurses to minimize the crippling aftereffects of poliomyelitis and to prevent deformities in its victims. Therefore, since 1940 we have approved a series of grants to the National Organization for Public Health Nursing totalling \$125,950 to train and instruct capable supervisors and directors in orthopedic public health nursing. Up to the present time, 48 scholarships have been awarded, and the National Foundation will continue to support and finance this project which is contributing substantially to the general effectiveness of official health agencies.

Unfortunately, the personnel problem cannot possibly be handled by public health organizations within the limitations of their budgets. The recruiting of qualified individuals is not accomplished in haphazard fashion. For the past 2 years we have underwritten to the extent of \$25,350 the American Public Health Association's field consultation service to state and local health departments in connection with recruitment and selection of personnel and the maintenance of sound personnel procedures.

The same organization was further aided by a 2 year grant of \$10,000 to acquaint city, county, and state health authorities with the importance of the sanitary engineer in maintaining a healthy environment.

It becomes quite evident then that, rather than working in opposition to public health agencies, the National Foundation has maintained a policy of direct assistance in the building of sound, vigorous official organizations, capable of leading the fight against disease within their communities. But it still rests heavily upon voluntary agencies—specialists in their field—to carry on the bulk of the work in combating a specific disease. Every advance that the National Foundation makes against poliomyelitis is an accomplishment in control of all diseases. Every research project carried on with the financial support of the National Foundation is a major effort in the quest for national health. Whether we represent voluntary, private or official health agencies, our goal is the same.

By working hand in hand, by co-operating willingly and energetically, we may look forward to new accomplishments in the service of the American people—and of all humanity.

Coördination of Hospitals and Health Departments

Joint Statement of Recommendations by the American Hospital Association and the American Public Health Association *

THE American Hospital Association and the American Public Health Association have prepared this statement to define the areas in which fuller co-operation and integration of hospitals and health departments may be achieved. The statement is confined to an exploration of these areas and does not concern itself with other aspects of either hospital management or community health organization. It is hoped that hospitals and health departments will find it a useful guide to their attainment of closer working relations in the interests of greater efficiency and improved health service.

Among the foremost institutions which today serve the health of the community is the general hospital. Not only has the hospital developed during the past few decades into the basic institution providing the technical facilities for adequate health appraisal and modern diagnosis and treatment of disease, but it has also become an indispensable workshop for the practising physician. Through its ability to make essential technical procedures available to physicians and other personnel the hospital exercises a strong and direct influence on the quantity and quality of medical and health services.

Because of its important position the general hospital's responsibilities in the

total community health picture have been constantly expanding. In addition to the provision of facilities for medical care of high quality, its functions now include training of medical and allied personnel, medical research, and participation in local public health activities.

Profound changes and advances in the activities of health departments have paralleled this expansion in hospital functions. The achievement and maintenance of ever higher levels of community sanitation is making it possible for health departments to turn increased attention to developing programs to improve individual health through immunization, education, and health supervision; at the same time they have found it essential to provide therapeutic services if communicable diseases such as tuberculosis and syphilis are to be effectively prevented. Health departments have begun to recognize the important public health implications of such major health problems as cancer, heart disease, and other long-term illnesses and to combat them by providing certain facilities to aid in early diagnosis and treatment. In order to secure maximum effectiveness for these campaigns they have begun to develop increasingly closer relationships with hospitals and practising physicians.

Preventive and curative medicine have reached the stage where they are no longer separable, and it is necessary at the present time to bring them together physically and functionally. The close physical and organizational association of health departments and hospitals will

* This report has been approved by the Executive Board of the American Public Health Association on the recommendation of the Committee on Administrative Practice and the Subcommittee on Medical Care. It has been adopted as an official statement of the two associations.

provide a valuable step toward this essential goal.

Hospitals and health departments have a common interest in providing the best possible technical facilities and administrative tools for the further development of both the preventive and therapeutic aspects of medical practice. The expression of this relationship in terms of greater coordination of the activities of hospitals and health departments has already occurred in some communities, but a great deal still remains to be accomplished in this direction.

HOUSING OF HOSPITALS AND HEALTH DEPARTMENTS

Since a considerable increase in the construction of hospitals and public health facilities may be expected in the next few years, it is appropriate that certain advantages of joint housing be pointed out at this time. It is strongly recommended that, wherever circumstances justify and permit, there should be joint housing of hospitals and health departments, and, if possible, the offices of physicians and dentists.

Although coordination of the activities of hospitals and health departments can be accomplished even if they are not closely integrated physically, it is most feasible when there is joint housing of the hospital and health department. The common use of laboratory and clinic facilities, which is difficult to achieve when the two institutions are physically separated, occurs readily when they are housed together. The planning of integrated programs is facilitated by joint housing and their administration is made smoother and more efficient.

Outpost rural areas

The health needs of rural areas which are isolated, thinly settled, and unable to support a general hospital may be met by the construction of outpost health facilities. These facilities would

house the offices of physicians and dentists, diagnostic facilities, the office of the local public health nurse, public health clinics, and in some areas a nursing unit for maternity care and minor illnesses.

The physicians whose offices are located in the outpost facility should be members of the medical staff of the nearest general hospital. Arrangements should be made for transportation of patients from the outpost area to the hospital and for consultation visits by the hospital staff to the outpost facility. Otherwise the outpost personnel may deteriorate professionally owing to their medical isolation or the outpost facility may attempt to undertake functions belonging properly in the general hospital.

Populous rural areas

The establishment of hospitals and public health facilities in many rural areas will require entirely new construction. It is recommended that in these areas hospital and health department facilities be constructed as an integral whole. It is particularly recommended that physicians' offices be included in the new structures so that the time and effort usually expended by private practitioners in shuttling back and forth between office and hospital would be minimized. This arrangement would facilitate laboratory and x-ray examinations of the physicians' patients, prevent unnecessary duplication of expensive technical equipment and make it easier for physicians to consult with their colleagues.*

Many advantages to the public, the health department, and the hospital

* The joint housing of hospitals and health departments has already been effected in a number of areas such as Sonoma, Monterey, and Kern Counties, California, and Washington, Charles, and Wicomico Counties, Maryland. In addition, plans to build combined hospital and public health facilities are under consideration in several counties in California; six districts in Manitoba, Canada; Etowah County, Alabama; Winston-Salem, North Carolina; Schoharie County, New York; El Dorado City, Kansas; and Eaton, Barry, Ionia, Allegany, and Van Buren counties, Michigan.

may be derived from joint housing of hospitals and health departments. A single health and medical center means greater convenience and continuity of service for the public. The pooling of resources resulting from joint housing enables the community to obtain more adequate facilities and better trained personnel than it could otherwise afford.

Through joint housing the hospital achieves greater prestige as the community center for all health and medical activities; it is able to hire a more competent staff by virtue of its increased financial strength and can therefore offer more comprehensive and effective service. Joint housing facilitates follow-up by public health nurses of patients after they leave the hospital, while the medical staff benefits from closer association with public health programs. Furthermore it may stimulate increased public interest in the hospital since more people will visit the institution for health promotion and preventive services rather than as a last resort.

The health officer likewise benefits professionally from more intimate association with physicians engaged in clinical medicine. His health programs receive added impetus from the increased knowledge and interest in public health gained by practising physicians, interns, and nurses. Case finding for public health programs in the hospital wards and outpatient department is facilitated. The health department attains new stature, dignity, and public understanding.

Where the general hospital already exists and health department facilities are needed, it is recommended that the latter be constructed as an addition to the hospital or adjacent to it, and that an understanding be reached between the two agencies concerning joint use of certain facilities in order to avoid unnecessary duplication. This plan, however, may not be practicable in some instances because of the isolated location of the hospital.

While it is administratively easier to combine the rural hospital with health department facilities when both are public institutions, there is little reason why joint housing of voluntary hospitals and public health facilities cannot be achieved.*

Urban Areas

In small cities with one existing general hospital it is recommended that health department facilities be constructed as part of or adjacent to the hospital wherever feasible. It may be more difficult to arrange for joint housing in cities with more than one hospital. Nevertheless, the difficulties are not insurmountable.†

In larger cities public health facilities should, in so far as it is logical and possible, be built as part of or adjacent to general hospitals. Of course this will not be feasible in neighborhoods which do not have hospitals. Where joint housing can be achieved it will have an important effect in improving the coordination and effectiveness of hospital and health department activities.

The cities in which medical schools are located present a special situation. In such cases the principal public health facility should be built on the grounds of the teaching hospital.‡

* In several counties of Maryland, for example, the health department pays rent for that portion of the hospital which it occupies, and the arrangement has proved highly satisfactory.

† In the city of Niagara Falls, New York, which has two voluntary general hospitals, plans are now being considered to construct the principal public health facility adjacent to one of the hospitals and to locate smaller centers at strategic places throughout the city. These plans were formulated with the help of the local medical society and both voluntary hospitals, and received their full approval.

‡ This is the plan followed in Louisville, Ky., where the medical school, teaching hospital, and public health department form a single, integrated medical center. In New York City, five of the municipal public health centers are adjacent to medical schools. The health officers hold faculty positions in the medical schools, and medical students serve clinical clerkships in the public health centers. There is no doubt that considerable advantages accrue to both parties from this arrangement.

PERSONNEL AND ADMINISTRATION

There are many ways in which health department and hospital personnel can work together effectively. In urban areas, for example, coöperative arrangements between hospital social workers and public health nurses can prevent duplication of services and increase efficiency. In rural hospitals and health departments, although medical social workers are not generally employed by the separate institutions, it should be possible to employ a medical social worker to serve both agencies where there is combined housing of the health department and hospital.

In urban as well as rural areas the public health nurse can provide continuity of care for discharged hospital patients by carrying out the treatments recommended by the physician and giving home nursing care and supervision. This is true not only for patients with communicable diseases but for all hospital patients, whether ambulatory or not, who require further home supervision or care. Physicians, hospitals, and health departments should together agree on and carry out simple and effective referral systems.

In many areas the shortage of public health nurses limits the possibilities of this type of service. Nevertheless in some rural communities the public health nurse is able to perform a substantial amount of bedside nursing care. In the cities there has been a significant trend toward the amalgamation of voluntary visiting nurse services with those furnished under the health department program, thereby improving service and increasing the potentialities of physician-hospital-health department coöperation in this field.

There are several ways in which the medical staff of the hospital can contribute to the activities of the health department. Arrangements may be made for members of the visiting staff to conduct specific health department clinics

on a part-time salary basis. Members of the visiting and resident staffs can instruct public health nurses in current medical advances and assist in the health department's educational program by lecturing to community groups. Such service by physicians contributes to the building of a close partnership of physician, hospital, and health department to meet the overall health needs of the locality.

Consideration should be given to broadening the concept of intern or resident training to include a definite period of time spent in a public health department approved for this purpose. This would improve the physician's understanding of the preventive approach to medicine and acquaint him with services available to the public through the health department and other community agencies.

The achievement of closer administrative relationships between hospitals and health departments does not come about automatically but requires careful and continued planning as well as administrative finesse. Where the health department and the hospital are jointly housed but under separate administration, joint conferences should be instituted and definite fields of administrative coöperation outlined to further closer and more harmonious relationships.

In those areas which have a small community hospital and health department the appointment of a single administrator for both organizations may be considered.* There is need for further experimentation in this field.

Closer coördination of the training of health officers and hospital administrators is needed to familiarize health offi-

* In Branch County, Michigan, for example, the health officer is also director of the voluntary general hospital. This arrangement has made it possible to offer sufficient compensation to attract a competent physician. It has also proved highly advantageous in achieving greater coördination of hospital and health department activities and a better quality of administration.

cers with hospital problems in view of their increasing responsibilities for hospital planning, construction, inspection, and licensure, and to develop hospital administrators and health officers who have sufficient understanding of each other's activities to coördinate them effectively. This would also make available personnel competent to direct combined hospital-health department units. Several schools of public health have already recognized the importance of such coördination by requiring one basic course of training for both groups and permitting specialization subsequently in either public health or hospital administration.

PREVENTION OF COMMUNICABLE DISEASE

The control of tuberculosis, venereal disease and other communicable diseases affords numerous opportunities for joint action by hospitals and health departments. Tuberculosis and venereal disease clinics belong properly at the general hospital, not at the city hall or some other non-medical institution. Likewise rapid treatment centers for syphilis should, in so far as possible, be housed in general hospitals rather than organized separately.

With present knowledge of the control of cross-infection there is very little reason for establishing special hospitals for the care of acute communicable disease. With the possible exception of large urban centers such special hospitals are economically wasteful and seldom provide services which meet the total medical needs of the patient. A more rational approach is to use general hospital beds for the care of patients with communicable disease and to obtain the assistance of the health department in developing effective isolation techniques. Such coöperative action will be facilitated if the hospital appoints the health officer to its medical staff as consultant in communicable diseases.

Routine chest x-rays as well as sero-

logical tests for syphilis ought to be undertaken by all hospitals. The interest of the health department in these health protection activities should take the form of substantial financial and technical aid. With such assistance every hospital can become a strategic center in the community attack on tuberculosis and venereal disease.

Close working relationships between general hospitals and tuberculosis sanatoria are necessary to afford sanatoria patients the advantages of modern surgical therapy as well as consultation services. For similar reasons a portion of the newly established hospital beds for tuberculosis should be located in or closely connected with general hospitals.

Laboratory service is essential to communicable disease control as well as to the proper functioning of hospitals. Health departments and hospitals have a vital interest therefore in the planning and development of adequate laboratory service.*

In some states hospital as well as health department laboratories are approved by the state department of health which, in addition, holds an annual educational meeting of laboratory directors and supplies them with current bibliographies on technical subjects. Marked improvement in laboratory standards has resulted from such procedures and they have been well received by hospital laboratory personnel.

PROGRAMS FOR NON-COMMUNICABLE DISEASE

With the progressive conquest of many communicable diseases attention has shifted to other major causes of

* In some of the rural counties of Maryland, the use of a joint laboratory has been found to be advantageous, since the additional financial resources allow the utilization of better trained personnel. In small cities with more than one hospital as, for example, Jamestown, N. Y., it has been found effective to have a single director administer the health department laboratory as well as the several hospital laboratories. This arrangement provides a well integrated laboratory service and enables the community to obtain a director of high caliber.

disability and death. Heart disease, cancer, and mental illness are rapidly becoming recognized as having significant public health implications. The epidemiological study of such diseases—their prevalence and relation to socioeconomic, environmental, and constitutional factors—can shed much light upon their origin, prevention, mitigation, and treatment. The social effects of non-communicable diseases, their chronic nature in many instances, their increasing importance as the population ages and the huge expense involved in their care put them beyond the scope of the individual physician or hospital alone and mark them clearly as among the most important public health problems of the day. Accordingly, there have been renewed attempts to construct adequate systems of morbidity reporting and greater emphasis has been placed on health education as a preventive device in the management of non-communicable disease.

Hospitals provide an effective environment in which to educate the public in health matters.* In addition hospitals are repositories of much valuable information on the incidence of disease which should be studied and utilized in the development of control programs. They occupy an important position in relation to plans for controlling heart disease and cancer and are natural locations for cardiac and tumor diagnostic clinics. The recent development of cancer detection clinics, in which apparently well persons receive thorough diagnostic examinations, promises to encourage greater concentration on this type of preventive activity by the staffs of general hospitals.

It has long been recognized that psychiatry suffers through its isolation from general medicine. Similarly the aver-

age physician, having received little or no training in psychiatry, is handicapped in his ability to recognize, treat or prevent mental disease. The importance of mental illness is indicated by a recent estimate that approximately 1 patient out of every 28 new admissions to general hospitals, and 1 out of every 16 new admissions to outpatient departments presents problems requiring the services of the psychiatrist.

Owing to the passage of the National Mental Health Act a large-scale development of research facilities and clinics for mental hygiene may be expected. In many areas the local and state health departments will be responsible for administering the mental health program and integrating it with other health activities. It will be to the best interests of psychiatry and medicine in general if hospitals welcome the establishment of mental hygiene clinics and incorporate their functions as part of a general hospital service. Large general hospitals should establish psychiatric services for observation and treatment of mentally ill patients and, wherever feasible, the medical staffs of general and mental hospitals should develop liaison in order to provide consultation services to patients of mental institutions and to furnish the patients of general hospitals with skilled psychiatric assistance. In this way a more fully generalized and comprehensive service to the community would be achieved.

MATERNAL AND CHILD HEALTH

Maternal and child health clinics should be easily accessible to the persons served and many must be conducted in communities or neighborhoods which do not have hospitals. Nevertheless, there are numerous instances where the general hospital is easily accessible but is not utilized for such services. This situation, which has arisen from the separate development of hospital and health department facilities, prevents both hos-

* This has been demonstrated by the excellent programs of The Johns Hopkins Hospital in Baltimore and the Shoemaker Clinic in Cincinnati.

pital and health department from operating at their maximum effectiveness in the protection of maternal and child health. Health department prenatal clinics for the adjacent neighborhood should be conducted in the general hospital in order to insure continuity of care, easy transfer of records, and adequate postpartum follow-up. Similar considerations apply to well child and pediatric diagnostic and treatment clinics. The maternal and child health clinics conducted by health departments in areas not easily accessible to hospitals should be affiliated with the central hospital clinics for referral of complicated cases.

Still other opportunities exist for closer relationships between hospitals and health departments. The latter can supply educational literature to hospitals for distribution by physicians to their maternity patients. The state department of health in particular can furnish consultation services by medical, nursing, nutrition, and other staff members. Hospitals can enlist the aid of the health department to prevent outbreaks of infant diarrhea and to develop comprehensive programs and facilities for the specialized care of premature infants, and should cooperate with the health department and practicing physicians in their review of maternal and infant deaths. The health department can assist hospital laboratories to make determinations of the Rh factor by furnishing consultation services, providing typing sera, or actually performing the tests.

All too often the public health nurse receives notice of the birth of a child several weeks after its occurrence and the mother is thereby deprived of her advice and assistance during the period when they are most important. This problem has been solved in some areas through cooperative arrangements by which the health department is informed of the birth before the mother and child leave the hospital. In many communities arrangements have been made with

physicians and hospitals for the public health nurse to see the mother while she is still in the hospital as well as make a preparatory visit to the home, thereby establishing the best possible conditions for adequate home follow-up.

The proportion of home deliveries is still too high in many areas. Hospitals should give serious attention to the provision of sufficient maternity beds to meet the needs of the entire community, particularly for the care of complicated cases.

MEDICAL CARE AND HOSPITAL SERVICES

A number of specialized medical care programs, including those for communicable disease, tuberculosis, venereal disease, and crippled children, are recognized responsibilities of health departments, and it is desirable that they be entrusted with new programs of community medical care which may be assumed by various levels of government. It would seem wise therefore for hospital and health authorities to undertake intensive research on several mutual problems. One of these, for example, is the creation of a satisfactory cost accounting system which will be equitable to both the hospital and the health department.

The experience of the last few years, particularly with the Emergency Maternity and Infant Care program, has established the important principle that the hospital receive full cost for the care of patients for which government assumes full responsibility. This precedent should be followed in all public medical care programs provided that an agreed standard of care is established and there is proper cost accounting.

In approximately three-quarters of the states the state health departments have been given the responsibility for hospital surveys and planning incident to the Federal Hospital Survey and Construction Act of 1946, and it is expected that they will be given similar

administrative responsibilities with respect to the construction phase of the program. This will inevitably encourage much closer relationships between hospitals and health departments than have ever existed in the past.

Hospital licensure laws have already been enacted in most states and with few exceptions the state department of health has been designated as the responsible agency. Much of the activity of the agencies administering such laws is of an educational character, designed to assist hospitals in improving standards of service to the public.

A significant expansion in the number of full-time local health departments as well as in the scope of their activities may be expected in the next few years. Similarly the nation's hospital system will be extended to many areas which now lack adequate facilities and greater emphasis will be placed on the community responsibilities of the general hospital. It is important at this time that hospital and health department administrators plan to achieve maximum co-

ordination through joint housing, cooperative use of personnel, and the development of active programs to safeguard and promote the health of their communities.

M. Terris, *Bull. Inst. Hist. Med.*, 20:387 (Oct.), 1946.

Description of Hermann M. Biggs' health center proposals of 1920, which included hospital and health department facilities in a single center.

7. The Health Center—Adaptation of Physical Plants to Service Concepts. J. W. Mountin, and August Hoenack. *Pub. Health Rep.*, 61:1369 (Sept. 20), 1946.

Discussion of four types of health center plans:

1. Those designed for public health agencies alone
2. Those that combine the hospital and public health agencies
3. Those that provide accommodations for the health department and practising physicians

4. Those that combine the health department, the hospital, and offices for practising physicians

8. Hospitals. U. S. Public Health Service. Reprinted from *Architectural Record*, Aug., 1945.

Blueprint of a coordinated hospital service plan, including plan suggestions for a 50 bed rural hospital and public health center and an outpost rural health center with 10 bed nursing unit.

9. Better Hospital Care for the Ambulant Patient. Hospital Association of Pennsylvania, Harrisburg, Pa., 1946.

Study of clinic services in Pennsylvania, with comprehensive discussion of the role of hospitals in relation to group clinics, health centers, and civilian rehabilitation.

10. Schoharie County Health Service. New York State Department of Health and the Joint Hospital Board, Sept., 1946.

Detailed report to a county board of supervisors on a combined hospital-health department unit.

Specific Programs

11. The Care of Acute Communicable Diseases in General Hospitals. Commission on Hospital Care, *Hospital Survey News Letter*, Jan., 1946.

A good analysis of the reasons why patients with acute communicable disease should be cared for in general hospitals.

12. Tuberculosis Control. *Hospitals*, Aug., 1946.

A portfolio of information on tuberculosis control prepared in collaboration with the U. S. Public Health Service, with special emphasis on the role of general hospitals and the routine use of admission chest x-rays. Articles on methods, finances, records, etc.

13. Health Education in Hospitals and Out-Patient Departments. Henriette Strauss. *A.J.P.H.*, 35:1175 (Nov.), 1945.

The experience of the Department of Preventive Medicine at The Johns Hopkins School of Medicine in organizing a health education program in the hospital.

14. Education While They Wait. Elisabeth M. Ferber. *Mod. Hosp.*, 66:63 (Apr.), 1946.

The use of motion pictures as a health education medium in the Shoemaker Clinic in Cincinnati.

15. *Hospital Licensing Act*. Council of State Governments, Chicago, Jan. 1, 1947.

A model hospital licensing act prepared by the Council of State Governments in cooperation with hospital, public health, and medical organizations.

PROGRESS IN THE STUDY OF ORGANIC INSECTICIDES

TWO years ago, Dr. F. C. Bishopp¹ reviewed for us the status of DDT as a public health insecticide; and progress in this field has been so rapid that we have asked Dr. J. M. Andrews of the U. S. Public Health Service Center at Atlanta to bring the subject up-to-date, in the Special Review Article of this issue of the *Journal*. The importance of such a review is indicated by the fact that Dr. Andrews cites 134 articles bearing on the subject, most of them appearing within the past two years.

The use of DDT has been brilliantly justified by recent experience, particularly in dealing with malaria, with murine typhus, and with various diseases carried by sandflies. It has been useful in the control of the house-fly, but with certain distinct limitations, which the sanitarian should bear in mind. DDT is not effective against the larvae of house-flies and blow-flies, and certain strains of house-flies appear to develop special resistance against this insecticide in the adult state, a phenomenon analagous to the evolution of drug-resistant strains of various pathogenic microbes. It is clear that fundamental sanitary measures for the control of fly breeding cannot be neglected.

Dr. Andrews reviews suggestive studies of various solvents used with DDT and of new alternative insecticides such as Chlordane and DDD. He notes the importance of guarding against toxic effects, although "DDT when used as an insecticide, with reasonable intelligence and the precautions normal to the use of modern insecticides, is harmless to man and animals." He emphasizes the need for regulating dosage, when insecticides are applied on a large scale over wide unoccupied areas to destroy insects harmful to health, forest trees, or agricultural crops, so as to avoid upsetting the general balance of wild life.

All in all, we believe that this review will be of unusual value to our readers. The use of the new insecticides marks one of the major advances in the history of public health; and it inaugurates a far-reaching change in sanitary practice through the replacement of rule-of-thumb (or rule-of-nose?) nuisance control by scientific sanitation.

THOMAS PARRAN

THE United States Public Health Service has a history of a century and a half behind it (although for the first part of that period it was called the Marine Hospital Service and performed only the function of providing medical and hospital care for sailors of the Merchant Marine). Hugh S. Cumming, Surgeon General from 1920 to 1936, transformed the organization from a sound but somewhat pedestrian service to a vital and progressive one; and many of the outstanding leaders of the U. S. Public Health Service were brought forward to positions of influence under his regime. "Tom Parran," who succeeded him has presided with wise vision and courageous initiative over the most distinguished era in the history of the Service.

The following brief chronological list of the major new ventures undertaken during the twelve years of General Parran's service (which ended this spring), is an impressive record:

1937. Initiation of a National Research Program on the cause and cure of cancer.

1938. Initiation of a National Program for the control of venereal diseases (in which Dr. Parran's personal leadership was particularly influential in breaking down old prejudices and which has made most fundamental contributions to the administrative application of modern rapid-treatment methods).

1943. Organization of the United States Cadet Nurse Corps, which was of great value in meeting war needs.

1943. Radical reorganization of the structure of the Service, to secure greater efficiency in operation.

1944. Initiation of a National Tuberculosis Control program.

1946. Initiation of a National Mental Health Program, probably the most effective step ever taken in this or any other country; to translate talk into action in this most important and most neglected field of public health.

1947. Actual initiation of a nation-wide survey and construction program to develop essential hospital and health services for neglected areas.

Meanwhile, the outstanding program of research, at the National Institute of Health, has been continued and expanded, so that this Institute represents the most fruitful research agency in the field of public health anywhere in the world. Grants-in-aid to states, local health services, and institutions for expansion of public health work and research have averaged 13 million dollars a year in recent years, while for the same period expenditures by states have increased from 16 to 52 million dollars a year.

Dr. Parran had been released from 1930 to 1936 to serve as Commissioner of Health of the State of New York, where he built up—on the foundation laid by Hermann M. Biggs—one of the most outstanding state health departments in the country. In recent years he has made notable contributions in the field of international health, and presided at the New York conference where the Constitution of the World Health Organization was drafted in 1946. It is as the "S.G." however, that he is most widely known to us. It was primarily for his leadership of the U. S. Public Health Service that he received 16 honorary degrees, and the Sedgwick Medal and the Lasker Award from our Association. With no prejudice to his predecessors who served in less health-minded years, Thomas Parran stands today as the most outstanding Surgeon General of the world's most outstanding national health service. He is a young man of whom we shall hear more in the future.

THE BATTLE OF BRITAIN

THE new British National Health Insurance Act will come into force on July 5, replacing the present National Health Insurance program which on that date goes out of existence. At the present writing, the British Medical Association plans to refuse participation, supported by a two million dollar Fighting Fund (described by the lay press as a "Strike Fund"). Feeling on both sides is bitter. The *British Medical Journal* raises the cry of governmental dictatorship, and frankly appeals to "emotion as the driving force behind reason and action." The *New Statesman* says that the British Medical Association is "seeking to debase" the generous motives which animate the healing art "by arousing emotions which, when they are sincere, are mistaken, and, when they are less than sincere, are a betrayal of the doctor's calling and of the loyalty and affection of his patients."

The conflict is a tragic one; and it is important for us, in the United States, to understand what the shooting is about. Many Americans have been led to believe that it concerns the basic principles of compulsory health insurance; but this is not the case. England has had compulsory health insurance for more than thirty-five years. "All concerned, doctors as well as public, recognize the need for a National Health Service; all accept broadly the structure of the Act in regard to the whole hospital system; all realize that there must be a public medical service based wholly or mainly on capitation fees. This is as it should be; fundamentally this is a good Act; its provisions are better than most previous proposals and it gives to doctors themselves a far larger representation than they did have—on Executive Councils, Appeal Tribunals, Medical Practices Committees, and the rest—in the administration of the Act."¹ The negotiating committee of the medical profession itself pointed out that "such differences as have arisen between the government and the main body of the profession relate not to the objective itself (the establishment of a comprehensive medical service), but to the means proposed to achieve the objective."

The issues which divide the medical profession from the government are four in number:

The first of these, and the one which perhaps bulks largest in discussion, is the provision of the Act which establishes a basic salary of 300 pounds for every physician, to which will be added capitation fees based on the number of families served. It is estimated that a moderate practice should yield a total income of 2,000 pounds. The basic salary is included in the Act to make sure that the young physician just starting in practice shall have at least a minimum income while he is building up his panel practice. The British Medical Association resents this as an "entering wedge" for the principle of salaried service and proposes a higher capitation scale as an alternative.

A second bone of contention is the provision in the Act that practices built up on a panel basis in the future cannot be sold by a retiring physician to a potential successor. (The government has arranged to recompense all physicians for the cash value of practices existing prior to July.)

A third point of conflict is the provision in the Act that if a physician wishes to move to a new area, he cannot take a panel practice in that area without the permission of the committee representing the panel doctors in that area. Private practice for the well-to-do, as well as consulting service by specialists, will be, of

course, entirely free; and the decision whether local panel practice is sufficient to warrant an additional panel practitioner is made, not by any government official, but by the local panel practitioners themselves. A fund of 400,000 pounds is provided for inducements to physicians to serve in "under-doctored" areas.

Fourth, the British Medical Association objects to the fact that the decision of a local executive committee (50 per cent medical) to remove a physician's name from the panel list can be appealed only to a special tribunal composed of a lawyer appointed by the Lord Chancellor, a medical practitioner appointed after consultation with the medical organizations and a third, with experience in local executive committees. A decision of this tribunal unfavorable to the physician concerned may be vetoed by the Minister of Health, but not a decision favorable to him. The British Medical Association demands further appeal to the lay courts.

There have been certain minor points at issue; but these are the four major factors which threaten to produce a "Doctor's Strike" in Britain next July.

No one in this country can fully evaluate the issues involved; but such journals as the *London Spectator* give us a picture of the trend of public opinion in quarters sympathetic with the medical profession. Such opinion is reasonably unanimous in supporting the Minister of Health on points 3 and 4 above (avoidance of excessive competition for panel patients in an "over-doctored" area and prohibition of the sale of public panel practices). The opposition of the British Medical Association to these two provisions seems to have little public support. On the fourth point, right of appeal from the Minister of Health to the Courts on the part of the practitioner removed from a panel, public opinion seems generally to back the new Act; it would seem, however, that a concession on this point to the British Medical Association would not do anyone serious harm.

The first issue listed above, the basic 300 pound salary, would also appear to be properly open for conference and possible reconsideration. The purpose of this provision is an excellent one. Such a salary was included in the report of the Medical Planning Commission, representing the British Medical Association and other medical bodies, in 1942. Yet the present opposition to this basic salary is so strong that its elimination or modification might well be considered.

The *London Spectator* said—before the result of the doctors' plebiscite was known—"It is of cardinal importance that the Act shall come into force on the appointed date, now less than five months distant, and that it shall be worked not by men driven into a corner against their will, but by a body of practitioners determined under conditions which satisfy them to do their best for the health of the nation, as every doctor is doing today. Difficult as the situation is, there is no reason why this should not happen, for sharp though certain outstanding differences may be, none of them is incapable of adjustment. There can be no ultimatum to the doctors; nor can there be one by the doctors. When the result of the plebiscite is known some kind of contact between the Minister and British Medical Association must be reestablished. And the public, for whom this Act was devised and who need it urgently—particularly that large middle class, uncovered by National Health Insurance, on which a long illness or a serious operation falls with such crushing financial weight—must insist that outstanding questions be thrashed out between reasonable men in a spirit of common sense."

THE JOURNAL INDEX

THE last issue of this *Journal* was devoted to books; but to the scientist in any field periodical literature is equally important, and often more difficult to find when you want it. How often have you wondered where you saw that typhoid epidemic described or where that excellent article on health education appeared?

You will find the answers, so far as our *Journal* is concerned in a complete Index of its first 35 volumes (1911-1945). The preparation of this Index by Louise Pickens Tanner and Fred Wilbur Tanner has been a labor of love for which the Association owes these authors a deep debt of gratitude. It covers original communications, editorials, committee reports, and Association news, cross-indexed by subject and author; and occupies 335 pages of text. Here, you can find reference to what Biggs said about tuberculosis in France in 1918, to what Chapin wrote about air and contact infection in 1912, and to Sedgwick's Presidential address in 1913. This volume will be invaluable for our members and for students of public health in every country.¹

Clearing House on Public Health Salary Information

Salaries in State Health Departments

IN February the State and Territorial Health Officers Association released the study of salaries of state public health workers prepared at its request by the U. S. Public Health Service.

The study represents actual salaries paid * state health officers, 9 selected program directors, and 6 occupational groups of public health workers in the employ of state health departments in November, 1947 — medical, nursing, sanitary engineering, sanitation, nutrition, and professional laboratory personnel. The study does not represent a detailed job analysis of positions. It is therefore based on comparable titles which do not always represent comparable levels of responsibility. In spite of its lack of statistical refinements, this study serves a useful purpose in focusing attention on salaries.

Nor does the study indicate desirable salary levels. For practically all titles studied the salaries range widely among the 48 states. The highest salaries paid by a few states may not be within reach of all states, but it is certain that in most instances median salaries or less will not produce substantial responses from applicants.

The data of the study are shown entirely in the form of charts. These are of three kinds: bar charts showing in descending order the amount paid state health officers and bureau directors in 9 categories; bar charts showing salary ranges for 8 groups of workers in rela-

tion to number of persons in each salary class; and tables showing number of workers in the eight groupings in various salary classifications in each state, the states grouped in the U. S. Public Health Service Districts.

State health officer annual salaries range from \$5,000 to \$15,000, but in only 7 states were they as high as \$10,000. These states are in New England, the Middle Atlantic, South Eastern, and Pacific Coast regions. The median was \$7,500 which is also the mode and was paid by 10 states. In 17 states the health officer's salary was less than \$7,000, and in 6 states less than \$6,000. For directors of local health services salaries ranged from \$4,500 to \$9,600.

Of the directors of medical specialties, the director of tuberculosis control activities appears to be slightly in the lead. The range of salaries and the number in certain salary groupings are shown in Table 1 for three groups of medical specialties.

No medical personnel other than state health officers received more than \$9,000 except in one state. One such worker in each of 3 states in 3 different regions was paid less than \$3,600. A total of 133 workers, one-sixth of the number in this category, received less than \$5,000. These salaries were scattered among all regions except the Pacific Coast states.

State directors of sanitary engineering, of whom 47 were reported, were paid salaries ranging from \$4,250 to \$11,000. The median, paid in 3 states, was \$6,000. Nine state sanitary engineers

* Except in some instances in which position was vacant and minimum rate shown in the State Compensation Plan was used.

TABLE 1

| | <i>Maternal and Child Health Service</i> | <i>Veneral Disease Control</i> | <i>Tuberculosis Control</i> |
|----------------------------|--|--|---------------------------------|
| Number of States Reporting | 47 | 39 | 38 |
| Highest Salary | \$7,750 | \$9,200 | \$11,700 |
| Lowest Salary | 4,200 | 4,200 | 4,500 |
| Median Salary | 6,250 | 6,000 | 6,300 |
| Number Receiving | | | |
| \$7,500 and over | 2 | 3 | 6 |
| Less than \$6,000 | 18 | 15 | 11 |
| Less than \$5,000 | 7 | 6 | 4 |

received \$7,000 or more; 12 received less than \$5,000.

The median salary of the 446 sanitary engineers below the rank of directors was between \$4,000 and \$4,200; 44 per cent of the entire number received less than \$4,000 and one-seventh received \$5,000 or over. Seven persons in this category received \$7,000 or over. Nearly half of the salaries ranged between \$3,600 and \$4,400.

For this group of workers the median was the same in all areas except the Pacific Coast states where it was \$4,200–\$4,400 and the Mountain states with \$4,000. These two areas are less significant because of the small numbers involved.

Sanitation personnel is treated as a separate category throughout the study. In the effort to get a reasonably homogeneous group, veterinarians, entomologists, rodent, bedding, and drug and narcotic inspectors were omitted. Even this group of 1,388 workers represents a wide range of salaries and presumably also of qualifications.

Salaries of this group range from \$1,440 to \$9,200 with both the median and the mode between \$2,400 and \$2,600. Fewer than 1 per cent received more than \$5,000; and one-fourth less than \$2,400. Median salaries for this group vary rather widely for the different regions of the country. Only in the Eastern and Southern states, which employed two-thirds of the reported workers in this category, is the median as low as the national median.

In the Mountain, West North Central, and South West states the median is \$2,600–\$2,800; in the East North Central, \$3,000–\$3,200; and in the Pacific Coast states \$3,200–\$3,400.

This material also shows an interesting relationship between sanitarians and sanitary engineers. For all of the states a ratio of one engineer to three sanitarians is indicated by the figures. The range however is from practically an equal number of engineers and sanitarians in the East North Central states to more than six sanitarians per engineer in the 12 Southern states.

The ratios are shown in Table 2 by the U. S. Public Health Service districts:

TABLE 2

| <i>U. S. Public Health Service District</i> | <i>Engineers</i> | <i>Sanitarians</i> | <i>Ratio of Sanitarians To Engineers</i> |
|---|------------------|--------------------|--|
| Total | 446 | 1,388 | 3 |
| 1 | 124 | 278 | 2+ |
| 2,4 | 102 | 649 | 6+ |
| 3 | 92 | 117 | 1+ |
| 5 | 20 | 56 | 3— |
| 7,9 | 100 | 245 | 2+ |
| 8 | 8 | 43 | 5+ |

Laboratory personnel is divided into directors and one other group limited to professional workers. Forty-five states reported directors of laboratory services with salaries ranging from \$3,600 to \$10,000. The median was \$6,000. Twelve states paid less than \$5,000, and only 6, \$7,000 or more.

Nearly one thousand of the workers other than directors were reported with salaries ranging from less than \$1,400 to more than \$7,400. The median was between \$2,800 and \$3,000 and the

Credit Lines

FURTHER LIGHT ON THE PECKHAM HEALTH CENTER

The Pioneer Health Center in London (otherwise known as the Peckham Health Center) has been discussed in connection with the centennial meetings of the Community Service Society of New York which brought Dr. Innes H. Pearse and Dr. G. Scott Williamson to New York in March. The following notes supplement the information that is available in the volume *The Peckham Experiment—A Study in the Living Structure of Society*, by Innes H. Pearse, M.D., and Lucy H. Crocker, B.Sc., published by Yale University Press, 1945, 333 pp., price, \$3.50. (See *A.J.P.H.*, 34, 10:1103 (Oct.), 1944.

A conversation between the executives of national health agencies and Dr. Pearse brought out the following interesting factors:

Throughout the development of this plan the interest has been focused on insusceptibility rather than on susceptibility to disease. The center of interest is health rather than disease. The family is the unit, for all the thinking and planning and experience has shown that the earlier recognition of various derangements, both physical and psychological, gives a great advantage in prompt action and correction.

Dr. Pearse believes that the causation of disease lies as much in the environment as in the individual.

Being reluctant to invade the homes for case work, the group set up a recreational club to bring the people out on their own volition and to provide a center where the medical services could be carried out. Two thousand families have been included in this service, made up of about 8,000 individuals. A so-called "overhaul" examination was carried on 5 days a week from 2 to 10

p.m. Throughout this examination that which was right in the individual's health was sought rather than that which was wrong. In about 10 per cent of the persons nothing wrong appeared but this 10 per cent that was physically and mentally normal was not necessarily made up entirely of mature and well adjusted individuals.

Of the entire group, about 20 per cent came in with some disease or complaint and experience showed that at least half of these conditions were unknown to the medical profession. In this particular group money was not the primary reason for keeping people away from medical care.

One of the most prominent developments was the improvement shown by women in the capacity to carry on during pregnancy so far as family responsibilities were concerned.

The service made a point, since the family was a unit, not to forget the father of the family, who is usually away at work during the ordinary clinic hours.

A very clever means of admitting only those who were members and whose dues were paid was devised in individual keys for the door which automatically registered the attendance of the individual and would admit him only if his dues were paid. This method was also used in the study inside the center in studies of what is called the "Action Pattern."

A motion picture describing the Pioneer Health Center under the title of "The Center" is available in the United States from the Offices of the British Information Service, 30 Rockefeller Plaza, New York City.

ETCETERA

If you do not see the *Statistical*

Bulletin of the Metropolitan Life Insurance Company regularly, you should. Just as an example, the November, 1947, issue discussed "The Tuberculosis Problem—Retrospect and Prospect," the theme of which is "The time is ripe for an all out war to stamp out tuberculosis in our country," and significantly, "Side by side with these specific measures is the general effort to provide better housing and better living and working conditions generally for the people of our country."

Other articles in this issue are "The Chances of Being Born Alive," which we are told are determined by a variety of factors, among them "order of birth"; another estimates that the cost of the common cold is over a billion dollars a year and thus "must be rated high in the list of enemies of the public health."

The same issue reports a sharp increase in motorcycle accident fatalities, and on the other hand a decline in mortality from toxic goiter.

SOUTHWESTERN MINNESOTA HEALTH DAY

"Health Day" may come to be a technique for organizing communities to meet their health problems. At any rate, a group of six counties comprising the Southwestern corner of Minnesota along with the Southwestern Minnesota Medical Society and its Women's Auxiliary and the Minnesota Department of Health State District Health Unit in that area tried this technique late in February. Representatives of the Minnesota School of Public Health, farm and labor groups, public schools, nursing and welfare agencies, and representatives of the state health department all met in Worthington to discuss "Our Community Health Problems," "Farm and Home Safety," and "Mental Health in Child Development." The six counties participating in this "Health Day" have a total population of about

100,000 and make up one of the State District Health Units. This experiment in coöperation might be a first step in setting up a local district health unit. Further information can be secured from The Division of Public Health Education, Minnesota Department of Health, Minneapolis 14.

DOCTORS CONSIDER THEIR SOCIAL RESPONSIBILITY

"The Plight of the Negro Physician in American Medicine" was the subject of a recent public discussion held at the New York Academy of Medicine under the sponsorship of the Physicians Forum. Speakers were:

Montague Cobb, M.D., Professor of Anatomy at Howard University

Alfred E. Cohn, M.D., Rockefeller Institute for Medical Research

Curtis Flory, M.D., Chairman, New York County Chapter of the Physicians Forum's Committee on Civil Rights in Medicine

It is heartening to see physicians take some responsibility for understanding—and perhaps doing something about—the disadvantaged members of their profession.

"THE ANNUAL," WESTERN BRANCH A.P.H.A.

There has recently come from the press, under the auspices of the Western Branch American Public Health Association, a first issue of *The Annual*, representing a résumé of papers presented at the first post-war meeting of the Western Branch held in San Francisco in May, 1947. This excellent publication was made possible through the contributions of several pharmaceutical houses to the Western Branch.

The five chapters include papers on Preparation for Public Health, on Mental Health and Geriatrics in a Public Health Program, on Public Health Administration, on Housing and Community Planning, and on Communicable Diseases. Included are the

Presidential Address of Karl F. Meyer, M.D., and the address of Thomas Par-ran, M.D., Surgeon General, U. S. Public Health Service, on Expanding Responsibilities and Opportunities in Public Health. Other contributors are Drs. Charles E. Smith, Harold D. Chope, Edward S. Rogers, Robert H. Felix, Kent A. Zimmerman, Lester Breslow, Alfred M. Popma, Howard West, Florence R. Sabin, Malcolm Merrill, Arthur Ringle, L. J. Lull, J. S. Cull, Raymond V. Stone, Richard K. C. Lee, James H. Steele, W. R. Giedt, G. L. Dunnahoo, and William McD. Hammon. The field of health education was covered by Dorothy B. Nyswander, Ph.D., that of graduate training in the West for nurses by Miss Mary J. Dunn, that of engineering training by Professor Harold B. Gotaas, and housing by Charles L. Senn and Allan A. Twichell.

The officers of the Western Branch are to be congratulated on having produced so commendable a volume in spite of the difficulties. The Publication Committee was under the Chairmanship of Richard A. Koch, M.D., San Francisco.

"CRADLE TO THE GRAVE" SOCIAL SERVICES OUTLINED

If, as has been said, a country may be judged by the way it cares for its children and its aged folk, there is plenty of evidence now available for judgment to be passed on modern Britain.

The evidence has just been summarized in a pamphlet *Social Services in Britain*, produced by the British Information Services, 30 Rockefeller Plaza, New York 20. This summary not only includes welfare schemes for the very young and the very old in Britain, but also the new security measures covering the sick, the unemployed, expectant and nursing mothers, widows, parentless children, the industrial injured, and even the decent disposal of the dead.

In other words it demonstrates Britain's claim to care for its citizens "from the cradle to the grave."

PREVENTIVE MENTAL HYGIENE IN WELL BABY CLINICS

Beginning in October, 1947, the Baltimore City Health Department in its Eastern Health District began a program designed to make preventive mental health a part of the general public health services offered in the well baby and maternity clinics. Before the program was started seminars were held for physicians and nurses to outline preventive mental hygiene possibilities in their maternal and child health work.

This program, together with an "Outline of Mental Hygiene in Maternal and Preschool Child Health for Public Health Nurses" is described in *Baltimore Health News* (25:1-2 (Jan.-Feb.), 1948), which is available from the Baltimore City Health Department, Municipal Building, Baltimore.

DISINFECTING WATER MAINS

"A Procedure for Disinfecting Water Mains," appearing in the February issue of the *Journal of the American Water Works Association*, is a report approved by the A.W.W.A. Board of Directors on September 30, 1947. It suggests both preventive and treatment procedures to minimize the possibility of contamination of a water system. The laying of new systems and repairing of existing ones are also covered.

ENGLISHMAN SUGGESTS A HYGIENIC FORK

The author of *A Hygienic Fork*, I. Gordon, M.D., Edin., Deputy Medical Officer of Health, Ilford, Essex, England, calls attention to the fact that very little change has been made in the design of tableware as a means toward better eating utensil sanitation. He suggests a three pronged dinner fork having tines half the length of those in the con-

ventional fork, with the edges and bases of the prongs bevelled for greater ease in cleaning. This article appears in the August 9, 1947, issue of *The Lancet*, a weekly British medical journal.

BERNARD BARUCH ON MEDICAL CARE

The Committee for the Nation's Health has made available reprints of Bernard M. Baruch's address on *Medical Care for the People of America*. This was recently delivered at a dinner sponsored jointly by the Medical Society of the State of New York, The Coordinating Council of the Five County Medical Societies of Greater New York, and the Greater New York Hospital Association. In this he says "I would not be frank—nor friendly—if I did not add what you know. Voluntary health insurance is not enough." Available from Committee for the Nation's Health, 1790 Broadway, New York 19.

A SURVEY OF OPERATING DATA FOR WATER WORKS IN 1945

The February, 1948, issue of the *Journal of the American Water Works Association* reports on a survey of basic financial statistics of water works systems in the United States. This survey is based on a report of a committee authorized by the Board of Directors of the A.W.W.A. These data were compiled from questionnaires sent to the executives of properties in the United States serving communities of 10,000 or more. Of these, 462 were returned, representing approximately 50 per cent returns. Data for each community on population served, source of water supply, controlling agency, volume of water provided, expenses, and income are included.

PUBLIC HEALTH IN BRAZIL

Several articles on tropical medicine and sanitation in Brazil are contained in the July, 1947, volume of the *Journal of the Servico Especial de Saude Publica*.

Included are data on the incidence and mass treatment of intestinal parasitism in the valleys of the Amazon and Rio Doce Rivers, experiences with DDT and pyrethrum in the control of *Anopheles darlingi*, and a report on the construction of municipal water supplies in the area of the Rio Doce. Also included are a number of keys to the identification of Brazilian anophelines.

The Servico Especial de Saude Publica was created by an agreement between Brazil and the United States, represented respectively by the Ministry of Education and Health and the Institute of Inter-American Affairs. Operations have been continuous since 1942 with particular emphasis on public health practices in the more remote regions of Brazil.

100 YEARS OF PIONEERING

The Community Service Society of New York completes its first century in 1948. By way of celebration it is holding a series of symposia on "The Family in Tomorrow's World." Symposium II on March 17 and 18 concerned itself with "Health and Family Life." Among the speakers were Martha M. Eliot, M.D., President of the American Public Health Association, Professor C.-E. A. Winslow, Editor of the *Journal*, Hugh Leavell, M.D., of the Harvard School of Public Health, W. R. Aykroyd, M.D., of the United Nations Food and Agriculture Organization, and Bailey B. Burritt, Executive Director of the National Health Council, who for 30 years was General Director of the Community Service Society.

The memorial volume published in connection with the centenary celebration is a handsome book entitled *Frontiers in Human Welfare*. It is a thrilling story of the movements this agency, one of the oldest in New York City, pioneered. They are large in number and varied in interest—tenement house reform, milk inspection, visiting nurse

service, social service education, case work standards, nutrition service, old age care, fresh air camps, and a multitude of others.

For information about the published proceedings of the symposia and about *Frontiers* write Community Service Society, 105 E. 22nd St., New York.

WILL DALLAS LEAD THE WAY?

The following editorial appeared in the *Dallas Morning News* for February 23. Is this a harbinger of local government organization in which consolidated health units will lead the way? Whether a flash in the pan or the beginning of a trend, it deserves the consideration of every public official—health and otherwise.

One-fourth of the nation's population is without adequate health service, Dr. Haven Emerson, member of the American Public Health Association, says. He blames lack of funds. There aren't enough funds for all the departments, but the big trouble is too many departments.

The forty-eight states have some 18,000 local health units. That figures out an average of about six departments per county. Dr. Emerson, recognizing the inefficiency in this multiplicity, says 1,200 departments can do the job, or an average of about one health department for every three counties.

Drop Dr. Emerson's criticism right in the middle of Dallas County, and it is apt. We have twice as many health departments as we need. To go further, we have twice as many tax offices and policing agencies as we need. To go further, Texas has twice as many counties as it needs.

Until there is a sensible merger of these services, they are never going to be what they ought to be. As long as we have a county tax office that is king bee in its own sphere and a city tax office in its sphere, the tax payer is going to suffer in his sphere.

Unified control, uniform regulations and enforcement, permanence of policy, and tenure for employees would give Dallas County a public health service that would be the envy of the state.

The day will come, of course, when not only city and county services are consolidated, but the consolidation of services of several contiguous counties will be effectuated. A

boundary will be meaningless when urban centers run into other urban centers. In the meantime, merging Dallas's two health departments is a sensible step toward the efficiency the tax payer deserves.

PIERRE THE PELICAN SERIES

The Louisiana Society for Mental Health, Hibernia Building, New Orleans 12, has produced a series of pamphlets which is being distributed to the mothers of new-born babies, one pamphlet a month for twelve months. These pamphlets are designed especially for the parents of first-born children and are unique because of the simplicity and highly focused interest.

According to Lloyd W. Rowland, Ph.D., the Director of the Society, the reading level is the sixth grade and several unique educational devices have been included. The series has been prepared for "a highly motivated group" and the conversations have been put into a little character invented for the purpose—Pierre the Pelican. He carries the discussion through and gives continuity to the pamphlets and succeeds rather well in keeping the discussion from becoming long-haired. Quiz forms have been cleverly used at the end of each pamphlet.

The series is already being used in West Virginia and certainly the idea will have appeal elsewhere. Among those who have been consulted with reference to the series are Dr. C. Anderson Aldrich, Professor of Pediatrics of the Mayo Foundation; Dr. Milton J. E. Senn, Associate Professor of Pediatrics in Psychiatry at Cornell University Medical College, and Dr. Robert L. Sutherland, Director of the Hogg Foundation for Mental Hygiene at the University of Texas. Specialists from Ohio State University have been used to adjust the language to the proper level. It is gratifying to see an unusual piece of work so well done. It is worth the attention of other state departments of health and of mental hygiene.

FOOD HANDLERS' SCHOOLS

Food Handlers' Schools in Hawaii describes the preparation and actual presentation of a course of instruction for food handlers. Suggestions are given on such subjects as selecting the time of day for classes, location of the school, size of class, extent of records, and literature to be distributed. Discussed also are publicity, program content and methods of presentation, illustrations of charts used, and photographs of laboratory preparations demonstrated as part of the course. This report, prepared by B. J. McMorrow and F. A. Schramm, appears as *Supplement No. 199* to Public Health Reports of the U. S. Public Health Service.

PTA FOLLOWS THROUGH

The April *National Congress Bulletin* of the National Congress of Parents and Teachers, in an open letter to its local presidents from its national president, Mrs. L. W. Hughes, brings its members up to date on the Local Health Services Bill (S. 2189, H.R. 5644, H.R. 5678) sponsored by PTA. Mrs. Hughes summarizes the action of her agency's February Health Conference and suggests how each local chapter may stimulate community health planning. The same issue carries a digest of the Local Health Services bill by PTA's legislative chairman, Mrs. Stanley G. Cook.

ANNUAL REPORTS

Twenty-five Years of Public Health in New Mexico, the report of the first quarter century of the New Mexico's State Health Department, has just been published for the period 1919-1944.

It will be remembered that New Mexico is the only state with a mandatory health district law grouping the state's 31 counties into 10 health districts whose health departments are operated by local boards of health with the coöperation and assistance of the State Health Department. The events

that led up to this mandatory law passed in 1935 can be traced in this 25 year report. In 1921, for example, 5 counties had full-time county health officers, in 1922 three more were added, in 1924 two more. But in 1926 two fell by the wayside and in 1927 another. The doldrums of the early 30's gave rise in 1932 to the first recommendation to restrict the state for health purposes.

In the meantime recurring frequently in the various biennium reports are such comments as "Our record in respect to diphtheria is not one of which we are proud" (1921-1922); "this biennium also witnessed typhoid outbreaks" (1923-1924); "occasional cases of malaria have appeared in two new areas of the state" (1925-1926); "the infant mortality rate is the highest in the United States" (1931-1932); "New Mexico has the highest infant death rate in the United States" (1937-1938).

A final chapter on the present health status of New Mexico points out that the infant death rate is still the highest among the 48 states; that the tuberculosis death rate is among the highest; the death rate from infectious and contagious diseases is three times that of the country as a whole. More than two-thirds of its dwellings have unsatisfactory sewer connections compared to 35 per cent in the entire country. This document should be the bible of things done and still to be done for citizen groups who want to start a movement for better health protective services.

Our hats off to the State Health Officer, James R. Scott, M.D., and his staff for telling the bad news as well as the good. Only in this way can come to pass the hope expressed "that the report on fifty years of public health may delineate the progress toward a more satisfactory status in the field of public health."

"Balance Sheet 1947" is the sub-title of the December, 1947. *Oakland's*

Health. This is the annual summary of the Oakland, Calif., City Department of Public Health. It has a Credit and a Debit section as well as A Job for the New Year—an interesting idea for a brief annual report.

The *1947 Annual Report of the National Social Welfare Assembly* is a brief summary of the activities and developments of the second year of this organization.

The *1947 Annual Report of the Social Security Administration* is the first report since its establishment in July, 1946, under the federal executive reorganization. It includes the report of the Bureau of Old Age and Survivor's Insurance, of Employment Security, and of the Children's Bureau. Along with

the annual report of its companion agencies, the U. S. Public Health Service and the Office of Education, it is an analysis of the social welfare services of the federal government.

Has the Tide Turned? is the 34th annual report (for the year 1947) of the American Social Hygiene Association. It is a good brief and graphic description of the Association's current activities. The title suggests that in 1947 some of the ground lost during the post-war years 1945 and 1946, when the country experienced a spectacular rise in reported cases of syphilis and gonorrhea, was regained. The last year also saw the development of the extensive worldwide service in stimulating social hygiene activities.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Recent Advances in Public Health
—By J. L. Burn, M.D., D.Hy., D.P.H.
London: J. & A. Churchill Ltd., 1947.
409 pp. Price, \$5.00.

This book is a condensation of the enormous social advances of modern Britain in public health. It does not attempt to present a complete picture of public health progress. While including a broad coverage, even Municipal Foot Health Service and Welfare of the Aged, greatest emphasis is on maternal and child problems. There are detailed accounts of mental health services, the care of unmarried mothers, the handicapped child, including blind, color blind, squint, deaf, speech defects, tonsils, and asthmatic, the diabetic, the rheumatic, and the child with cerebral palsy. The author assumes a broad fundamental background and the book is for the professional public health worker. There are detailed accounts of diphtheria immunization procedures and of tuberculosis mass x-rays. The "social" permeation is seen even in venereal disease control, which emphasizes contact investigation and followup rather than penicillin treatment of syphilis. Reliance on health education, of persuasion rather than compulsion, will make every American health worker appreciate the similarity of our democratic processes.

The presentation includes many classic discoveries and thumb-nail descriptions, such as the famous M'Gonigle report on housing and health, showing that the higher rents of rehousing may deplete nutrition and increase death rates, the superb contributions of Pickles to rural epidemiology, and the unique

Pioneer Health Center at Peckham. One tours the famous Papworth Village Settlement where the tuberculous work in a fashion which would make most American phthisiologists shudder and where, without benefit of BCG, the children of the tuberculous enjoy a remarkable healthy life without being removed from the tuberculous family. There is a summary of the remarkable experience at North and South Shields on the caries-detering effect of optimal fluorine in the water.

The index is very poor, but this is a book to be read in its entirety. This is very easy, for illustrations are profuse and smart, and the phraseology and expressions are just enough different to be very lively. For instance in the section on "Defective Colour Vision," the author remarks on resultant social difficulties, such as "the man who wore a red tie by mistake at his mother-in-law's funeral." In the description of the Recuperation Centres for the care of exhausted mothers we read: "As one mother put it: 'I should never have had the pluck to have all my teeth out at home.'" Even the one gross error in fact arouses only an indulgent smile. In relating the American experience in smoke control, he discusses the experience of St. Louis, Minnesota—"St. Louis was the dirtiest city in Minnesota." Although most references are to British experiences, the "U. S. A." comes in for many, as do Canada, the Continent, Scandinavia, and the U.S.S.R. Each chapter begins with a pungent text and closes with excellent selected references and valuable further reading suggestions.

This is a book which every public health worker in the United States and Canada can read with real profit and genuine pleasure. Burn will personally guide you on a trip through Britain and will frequently surprise you with penetrating observations on your own practices. CHARLES EDWARD SMITH

Atlas of Bacteriology—By R. Cranston Low, M.D., and T. C. Dodds. Baltimore: Williams & Wilkins, 1947. 168 pp. 168 illus. Price, \$8.50.

The purpose of this atlas is to afford students accurate pictures to refer to in illustration of lectures, practical classes, and textbooks.

The pictures are made from color photographs for the most part, giving the source of the material, how it is stained, what it shows, and the magnification. The characters of the microorganisms are not given.

The pictures substantiate the great trouble the authors have taken to insure accuracy and the coöperation and trouble taken by the original publishers (E & S Livingstone, Edinburgh) in meeting the exacting conditions required. This is undoubtedly the best atlas this reviewer has seen, and the selection of material is very good. It will be valuable to anyone who requires an atlas.

The value of the book would have been enhanced by the inclusion of references to the technique of the staining methods used. Minor criticism may be made of three items: the method illustrated on page 63 is Dorner's method and not Fleming's; the gonococcus colony on page 38 is misleading as it must be an old colony rather than a young one; the color of the pigment of "*B. pyocyaneus*" on page 21 is much too blue. E. G. D. MURRAY

The Cerebral Palsied Child and His Care in the Home—By Viola E. Cardwell, R.N. New York: Association

for the Aid of Crippled Children, 1947. 196 pp. Price, \$1.00.

This book is a welcome addition to the literature on cerebral palsy as there is still a paucity of written material on this subject. It is a carefully compiled book, written for the Association for the Aid of Crippled Children.

Although it was primarily intended to be used in staff education for nurses engaged in orthopedic public health nursing, it contains valuable information for physicians, technicians, and others who are beginning to become interested in this highly specialized field. In fact, the layman who has had to cope with the problem in his home will be able to comprehend most of the material and find helpful suggestions in the text.

The book is a practical one as the author has drawn from recognized authorities and workers in the field. Discussed in the first few chapters are the etiologic factors, pathology, prognosis for rehabilitation, and the various clinical forms of cerebral palsy which have been recognized to date. The remaining chapters deal with such important topics as mental hygiene, education, types of treatment, and the place of each in the overall program for the cerebral palsied child. The text also takes up the necessity of recreation and vocational guidance for those not too severely handicapped.

The author also pays tribute to the various societies founded by laymen, particularly those in and around New York City, which have demonstrated to physicians, educators, and technicians the need for programs of specialized care in dealing with this highly technical problem. These few interested parents have aroused long delayed interest in the cerebral palsied child and his many problems.

Replete with pictures and drawings of special equipment needed in the care of this type of handicapped child, it is

which publishes it is made up of 46 learned societies, including the American Public Health Association.

In the 1947 edition of more than 1,100 pages, 146 authors discuss 27 subjects under 7 main headings. The volume is "an elbow companion for everyone interested in contemporary events." It is source material for an appraisal of the age in which we live and an instrument for keeping informed on America, which is the fundamental duty of citizenship.

The article on Public Health, one of seven included under the Medical Sciences under the larger title of "Science: Application and Principles," is written by William R. Willard, M.D., of the Yale University School of Medicine.

A valuable feature of the *Year Book* is a list of periodicals and of cognate societies and research institutions in each of the seven main subjects of the volume.

MARTHA LUGINBUHL

Planning for the Care of the Chronically Ill in New York State—Legislative Document (1946) No. 66A. P.P. 131—By New York State Health Preparedness Commission. Albany: Williams Press, 1946. 85 pp.

This Legislative Commission with many years of study of health and welfare problems behind it has prepared a document which, while directed primarily to conditions in New York State, should serve as a useful guide to procedure and planning in other states.

The Commission was buttressed by strong advisory committees on Planning, Medical Education and Research and Nursing Care. The Commissioners of the State Departments of Health and of Social Welfare were ex-officio members of the Commission.

The report is well organized and readable. It is replete with charts, graphs, and tables. The summary of licensure of nursing homes in 20 states, together

with detailed reporting on planning for the care of the chronically ill in other states (Connecticut, Illinois, Indiana, Massachusetts, and New Jersey) provide useful information.

Under the following headings the findings and conclusions are stated: Convalescent Care, Medical Domiciliary Care, Nursing Homes, Voluntary Homes for the aged.

This report will be helpful to all those who are now facing the problem of providing for the care of the chronically ill in their own homes, hospitals, nursing homes, and elsewhere.

ELLEN C. POTTER

Advances in Internal Medicine. Volume II—Edited by William Dock and I. Snapper. New York: Interscience, 1947. 642 pp. Price \$9.50.

Those who expect this volume to be a year book of internal medicine will be disappointed. The volume consists of thirteen articles, of the review type, dealing with subjects in which advances are being made. The topics include electrocardiography, circulation of blood, penicillin treatment, the Rh antigen, megaloblastic anemias, and nutrition, as well as fields of interest to the internist. The latter include angiography, surgery for hypertension, and lung disease, insect control, and problems related to aviation and deep sea diving.

Well selected, the articles are comprehensive; they are thoroughly done by experts. The volume will be of interest to internists, those who wish to become internists, and those who want to know how and where internal medicine is advancing.

W. A. DAVIS

Food, Nutrition, and Health—By E. V. McCollum, Ph.D., Sc.D., and J. Ernestine Becker, M.A. (6th ed.) Baltimore: Johns Hopkins University, 1947. 146 pp. Price, \$2.00.

This is the sixth edition of a little book that has been well received in the

past and which serves a useful rôle in informing health personnel and interested laymen in modern nutrition. The current edition has been mostly rewritten and includes an account of many recent findings in nutrition. It is by no means a textbook or reference book in nutrition, but it is not intended as such. There are no references and practically no discussion. It is well written and in non-technical language.

In addition to the usual sections on various nutrients there are chapters on certain foodstuffs, diet in relation to anemia, pregnancy, and lactation, weight control, preventive dentistry, etc., and suggestions on conserving nutrients in foods and menu planning. Many of these sections are very brief, amounting to only one or two pages. The reviewer questions the advisability of including in a book of this type any reference to such vague entities as vitamins B₃, B₁, B₅, B₇, etc.

On pages 42 and 43 is a table entitled "Summary of the Vitamins of Known Significance to Humans," which includes vitamin E, pyridoxine, biotin, and vitamin P which, so far as the reviewer knows, have no established rôle in human nutrition. A paragraph on fat and water appears to have been mislaid in the chapter on mineral elements.

There is a need for a book such as this one and it is well written. Public health would be improved if more public health personnel knew what was between the covers of this little book.

FREDRICK J. STARE

American Foundations and Their Fields—Part I—*Edited by William B. Cherin. New York: Raymond Rich and William Cherin Associates, 1947. 58 pp. Price, \$6.00 (4 parts).*

Public health workers will have reason to be grateful to the authors for an up-to-date review of American Foundations and their programs. This represents a sequence of publications

originally presented by the Twentieth Century Fund and more recently by Raymond Rich Associates.

The survey has been broken down into four parts. This volume includes the Foundations' fiscal years ending February 28 to July 1, 1947. Each Foundation has been asked to provide information relating to the date of its establishment, the source of its funds, its purposes, the methods of operation, the direct activities, the financial data, the availability of reports, and the list of officers. It is notable that a considerable number of these agencies which enjoy tax exemption publish no reports and some refuse all information. It would appear to the reviewer that such information as is here presented should be mandatory for all foundations as a condition of the benefits which they enjoy.

REGINALD M. ATWATER

Food Regulation and Compliance. Volume II—*By Arthur D. Herrick. New York: Revere Publishing Co. 655 pp. Price, \$10.00.*

In volume I of this work the author, after briefly recounting the early history of legislation for food control, presented a comprehensive discussion of regulation through labeling requirements. In the first volume as in this second book, the discussion is chiefly limited to the Federal Food, Drug and Cosmetic Act. Some few other topics are given mention, such as the Federal Meat Inspection law and the problem of second-hand and used containers.

This second volume deals primarily with the problems of adulteration and contamination of foods, of control of permitted colors and the methods of enforcement and prosecution, all from the standpoint of the Federal Food, Drug and Cosmetic Act. There is a well written chapter on Insanitary Premises and Processing which will be of special interest to the public health official concerned with food control. In

this part of the book the author shows how the former limited federal control over food products solely by means of chemical and bacteriological tests was weak and ineffective, and now through the new sections of the law giving the Food and Drug Administration authority to inspect plants and provide sanitary standards for production and distribution the federal control has been greatly expanded and enhanced. However, these sections of the federal law become operative (giving authority for plant inspections and setting of sanitary standards) only after it has been established "that proper sanitation is so lacking that the food (a) may become contaminated with filth, or (b) may have been rendered injurious to health."

The book deals fully with the administrative practices and enforcement methods of the U. S. Food and Drug Administration. It is a volume that will be especially valuable to health officials who come in contact with the federal food control activities. The book contains the organization of the U. S. Food and Drug Administration and, in an appendix, provisions of the Federal Food, Drug and Cosmetic Act relating to foods.

SOL PINCUS

Fundamentals of Immunology—
By William C. Boyd, Ph.D. (2nd ed.)
New York: Interscience Publishers,
1947. 503 pp. Price, \$6.00.

The author addresses himself "mainly to students and research workers." At the end of each of the eleven chapters the pertinent material is presented in condensed form as a summary. These brief accounts when read consecutively without reference to the text constitute an excellent picture of the current views of the principles of immunology.

In the full text the author has taken care to introduce each new concept with sufficient elementary explanation to permit the student new to the subject to grasp the ideas. However, the elemen-

tary material is usually brief enough to avoid interference with the use of the text by research workers who wish to find more advanced material.

The eleven chapters include discussions of "cell antigens," "blood groups," "anaphylaxis and allergy," allergy and immunity as regards bacteria, viruses, and parasites, and "laboratory and clinical technic." The subject of skin tests for susceptibility and immunity is treated rather briefly in an appendix to one of the chapters. The bibliographies at the end of the chapters are extensive.

This book is well written. It should accomplish the author's objective of presenting the fundamentals of immunology to students and research workers.

J. C. SNYDER

Medicine for Moderns—*By Frank G. Slaughter, M.D. New York: Julian Messner, 1947. 246 pp. Price, \$3.50.*

Medicine for Moderns is a frank, easily read discussion of the concepts, mechanisms, therapeutic approaches, and hopes of psychosomatic medicine. Written in popular style for educated laymen, it succeeds in avoiding both the extreme sensationalism so common in books of this nature, and the insult of "talking down." Dr. Slaughter's intense enthusiasm, as a convert trained primarily in surgery, leads him into some wishful thinking in relation to the curative and preventive values of personality psychometric testing. The essentiality of individualization warrants somewhat greater emphasis. However, the material is sound and well presented.

Following a brief description of the anatomy and physiology of the autonomic nervous system, the author takes up the more obvious of the psychogenic illnesses: peptic ulcer, spastic colitis, hypertensive disease, asthma, and the like. There is an obvious appeal for popularity in the emphasis placed upon the psychogenic factors responsible for

impotence and frigidity. One misses accentuation of the important fact that all these disorders are characteristically derived from varied and multiple etiologic factors, and that continued anxiety is but one of several influences.

The book can be recommended as background reading for the laity, and may also be of value to those medical professionals who are asymmetrically organicists, insisting that that which cannot be seen does not exist.

EDWARD J. STIEGLITZ

Sports for the Handicapped—By George T. Stafford. (2nd ed.) New York: Prentice-Hall, 1947. 334 pp. Price, \$5.00.

There are few more satisfying fields of endeavor within physical and health education than working with handicapped students or with disabled patients. Stafford, in this exceedingly helpful second edition has pointed the way to a continuous betterment of programs which deal with the atypical. His book will be useful wherever people are concerned about the organic, psychological, and social rehabilitation and compensations of those who must seek to live most with what they have.

Stafford has long believed, and demonstrated, that sports can be adapted to the disabled. Prior to the war physical education departments in colleges and in some high schools were moving in this direction, but not as rapidly as the need demanded. The human wreckage produced by the war gave impetus to experimentation and, through the efforts of people like Stafford, Daniels, Esslinger, Kelly, Elkins and others, a full measure of good was done the disabled by ingeniously adapting sports or creating new ones for these very special purposes.

This second edition presents excellent material for use with the personality or psychologically handicapped, the amputee, the deaf, the paralyzed, those with

faulty body mechanics, malnutrition, circulatory misbalances, and spinal deviations. There are useful suggestions throughout for physicians and physical educationists. It should be read, and used widely. DELBERT OBERTEUFFER

Artificial Pneumothorax in Pulmonary Tuberculosis—By T. G. Heaton, M.B. (2nd ed.) New York: Macmillan, 1947. 292 pp. Price, \$4.50.

The revised edition (1947) of this book presents a concise and selective report of an important part of a system of collapse therapy in phthisiotherapy. The contents are contained in 16 chapters carefully arranged and chosen to lend a proper continuity to the subject. The literature on artificial pneumothorax is enormous and the author's selection and classification of authoritative references represent careful study and timely abstracts. The statistical data are reduced to a minimum consistent with satisfactory explanations of the text. The departure from complicated tables is welcomed by the busy practitioner.

The author's excellent training and experience permit a crystallizing of thought on many controversial points, and his own expressed opinions reflect the good judgment of the careful clinician.

The public health physician interested in tuberculosis prevention and control will find in this book a ready "up to the minute" reference on the latest scientific thoughts about the treatment of pulmonary tuberculosis by pneumothorax. It will be particularly welcome in the tuberculosis division or clinics of the health department, and more especially if such outpatient department service includes post-sanatorium pneumothorax supervision and refill treatments.

It would be unusual indeed if every reader of this book would agree with the author on all debatable points. The purpose, however, is served in presenting

accurate thought-provoking material to serve either as a supplement to knowledge of the subject already gained or to stimulate the reader to obtain further detailed knowledge of pneumothorax therapy beyond the limitations of the book itself.

The reviewer believes that this stimulating book from Canada is a real contribution to the field of tuberculosis therapy and should be read, understood, and made available for reference by all physicians actively engaged in the practice of tuberculosis or in the general field of pulmonary diseases.

JOHN A. CARSWEL

Physiology and Pathology of the New-born—*Compiled by A. N. Antonov, M.D. Monographs of the Society for Research in Child Development. Vol. X Serial No. 41, 1945, No. 2. Washington, D. C.: Society for Research in Child Development, National Research Council, 1947. 217 pp.*

This volume is a publication of the Society for Research in Child Development of the National Research Council. It is a bibliography or index of material on the physiology and pathology of the new-born for the period 1930-1940. A. N. Antonov, M.D., of Leningrad, has made a valuable contribution by compiling this extensive bibliography concerning scientific articles from all centers of the world. At even a glance the reader is impressed with the international interest in the physiology and pathology of new-born infants.

The table of contents shows 38 sections, with such titles as Fetus, The Influence of Pregnancy and Labor on the New-born, Anthropometric Data, Metabolism of the New-born, Congenital Abnormalities and Malformations, Birth Injuries, The Respiratory System, Other Systems, and Infectious Diseases. The book is valuable as reference material.

The large number of scientific arti-

cles on physiology and pathology of the new-born is truly impressive and shows the vast amount of work that was done between 1930 and 1940 preparing the way for further scientific knowledge and its application today.

MARTHA L. CLIFFORD

Industrial Environment and Its Control—*By J. M. Dallavalle. New York: Pitman Publishing Company, 1948. 225 pp. Price, \$4.50.*

This is an authoritative work on industrial hygiene presenting the engineering phases of environmental control in the prevention of occupational hazards, and it is written principally for engineers. However, this book should be read not only by industrial hygiene engineers but also by industrial physicians who need to know the engineering phases of industrial health service and the extent to which the medical service must be backed up by competent engineering if satisfactory results are to be obtained.

The book has a notable preface which clearly states both the aims and scopes of environmental control as well as their limitations. The author discusses the influence of atmosphere, the estimation of atmospheric qualities, and the variations from the normal that constitute health hazards. Vibration, fatigue, illumination, and radiant energy are amply presented.

There is a discussion of the methods of ventilation and the design and construction of ventilating systems, exhaust systems, and dust collection systems, together with the control of bacterial infections.

Finally, there is an appendix which covers briefly regulations, standards, and desirable practices, including brief statements on medical service, first aid, physical examinations, and record keeping.

The author is to be commended on a most worth while book. 'A. J. LANZA

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, Ph.D.

"More About Our Ignorance"—Would you like to see a paper that, by example, tells you how to prepare a readable report in addition to passing on some information to you? Then search out this particular British health journal. The paper is about the much written up colds research they have been carrying on with human volunteers.

ANDREWS, C. H. The Common Cold. M. Officer 79, 6:55 (Feb. 7), 1948.

Incidental Intelligence—Butylacetanilide repels ticks for 10 days and works against chiggers, too—just in case you wish to protect yourself against either of these pests. You dip exposed clothing in a solution, it seems.

BRENNAN, J. M. Field Tests with Tick Re-

pellants. Pub. Health Rep. 63, 11:339 (Mar. 12), 1948.

Largely Undeserved Praise—If you would like to enjoy a mild case of swelled head, read this Britisher's account of his visit to America last fall. He saw everything that was good and nothing that was bad, apparently. I cannot forego just one quote: "Almoning, or as it is called in America, medical social work is developing apace, and a chair in this subject has been established at the University of Yale."

DALEY, A. Impressions of America. Public Health. 61, 5:77 (Feb.), 1948.

Muscles and Emotions—Fitness seems to be the ability to perform the

tasks of daily living without undue fatigue, and the qualities making this possible are those of the total personality for physical and psychologic factors cannot be disassociated. This definition works pretty well whether applied to athletes, laborers, sedentary workers, the handicapped or the aged. Measuring fitness is a complicated procedure not lightly to be attempted.

DARLING, R. C., *et al.* Physical Fitness. J. A. M. A. 136, 11:764 (Mar. 13), 1948.

Thirty Million Hungry Children—Says our President—back from a tour of Europe—the greatest need of children everywhere over there is MILK and more MILK. Someone should tell this to our statesmen who refuse us the margarine that would release for these children some of the surplus milk now being churned into unneeded butter.

ELLIOT, M. M. The Need of the Children. Survey Graphic. 37, 3:140 (Mar.), 1948.

Children First in Every Country—We have widespread evidence in Europe, this British reporter writes, of the unrest, bitterness, disease, and destitution existing among those who suffered as children in the early war years and are now approaching manhood. But the record is not all black, he concludes.

ELLIS, R. W. B. Effects of War on Child Health. Brit. M. J. 4544:239 (Feb. 7), 1948.

Of Human Interest—There isn't much here but what there is, is 22 Karat. Good public speakers never forget, the professor says, that "people are interested in people." Send out speakers, he advises, who can make people laugh, but he doesn't tell you where to get them.

HANNA, M. Good Public Relations Requires Good Public Speakers. Am. J. Nurs. 48, 3:163 (Mar.), 1948.

This Hits Babies Hardest—Crowd-

ing, flies, improper excreta disposal, and bad personal hygiene all were associated with diarrheal disorders caused by *Shigella* infection. But water, milk and other foods did not seem to be implicated.

HARDY, A. V. and WATT, J. Studies of the Acute Diarrheal Diseases. Pub. Health Rep. 63, 12:363 (Mar. 19), 1948.

Silver-Lining Department—Here is a striking bit of economics passed along to you for what it is worth; the average stay in hospital is now a third of what it was three decades ago, and it costs twice as much per day. An illness that used to cost the victim \$150 now costs him \$100 for his hospitalization.

MACLEAN, B. C. The Hospital as a Community Health Agency. Pub. Health Nurs. 40, 3:115 (Mar.), 1948.

After Twenty Years—Physical defects discovered in New York State school children dropped in incidence, during the past two decades—except dental defects. They increased.

MAXWELL, C. H., and BROWN, W. P. The Age-Incidence of Defects in School Children, Their Changing Health Status. J. Sch. Health 18, 3:65 (Mar.), 1948.

Thought-for-the-Month — Trickling down from on high comes the rain of life-giving subsidies—from federal treasuries to states and from states to the communities—to support competent local health services. What is needed in return is a welling-up from below—from local workers to state commissioners to federal officers—of grassroots advice to avoid arbitrary and bureaucratic rulings that may lower the effectiveness of this productive partnership.

MERRILL, M. H. Federal-State-Local Relationships in the Financing of Local Health Services. Pub. Health Rep. 63, 8:244 (Feb. 20), 1948.

In Union There is You-Know-What—America's professional men and

women are sharing neither the profits of business nor the bargaining power of labor, this authority says. The A.N.A. is demonstrating how better incomes can be secured without sacrificing professional ethics or resorting to demeaning tactics. Is this assertion of any interest to you?

NORTHURP, H. R. Collective Bargaining and the Professions. *Am. J. Nurs.* 48, 3:141 (Mar.), 1948.

Warning Against Clock-Training
—Even though you are an engineer or a technician or a statistician, and even though you have no babies of your own, you should read this paper. As the first discussant says, "It shows that material

can be presented in simple language and yet be of the highest scientific value." And that, Brother, is something you and every one of us jargoneers needs to learn.

SPOCK, B. Common Behavior Disturbances in the First Two Years of Life. *J.A.M.A.* 136, 12:811 (Mar. 20), 1948.

To Measure Under-Reporting —
Promising to be the first of a series of discussions on the adequacy of local morbidity reporting practices and ways to increase completeness, this paper gives some hint of the present weakness and variables.

WEST, M. D. Morbidity Reporting in Local Areas. *Pub. Health Rep.* 63, 11:329 (Mar 12), 1948.

THE 76TH ANNUAL MEETING

Boston, Mass., November 8-12, 1948

Hotel Reservation Form

The hotels listed below have rooms available for Association delegates at the rates indicated. Please note that NO RESERVATIONS WILL BE ACCEPTED DIRECTLY BY HOTELS. Make your reservation through:

The Convention Bureau, Boston Chamber of Commerce, 80 Federal Street, Boston 10, Mass.

| Hotels | Singles | Doubles | Twin Beds | Suites |
|----------------|---------------|---------------|----------------|-----------------|
| Bellevue | \$4.00-\$6.00 | \$6.00-\$8.00 | \$7.25-\$10.00 | \$12.00-\$15.00 |

- James D. Vagneur, D.V.M., 1846 N. 17th St., Grand Junction, Colo., City Veterinarian

The Committee on Administrative Practice will plan for occasions during the 76th Annual Meeting of the Association in Boston, November 8-12, when Dr. Buck's friends will have an opportunity to greet him.

Succeeding Dr. Buck as the Association's Field Director is Roscoe P. Kandle, M.D., M.P.H., who was associated with Dr. Buck during 1946 and who left the Association staff to become Director of the Bureau of Preventable Diseases with the New Jersey State Department of Health in Trenton. Dr. Kandle is well equipped to carry on. With him is associated Robert E. Rothermel, M.D., M.P.H., as Assistant Field Director. Both Dr. Kandle and Dr. Rothermel are currently engaged in a survey of the State of Pennsylvania at the request of the Pennsylvania State Department of Health and Governor Duff.

GIFT TO COMMITTEE ON CHILD HEALTH
At the first meeting of the Associa-

tion's new Committee on Child Health in New York on March 20, announcement was made of a gift of \$300.00 from the residual funds of the Association of Women in Public Health.

The Association of Women in Public Health, first organized in 1920, voted to disband late in 1947 and to join forces fully with the American Public Health Association. Its Treasurer, Dr. Susan M. Coffin, referred to the gift as a "humble dowry" presented at the time of what Dr. C.-E. A. Winslow termed her Association's "marriage with the American Public Health Association."

The new Committee on Child Health at its first meeting explored areas of cooperation with such agencies as the American Academy of Pediatrics, the Children's Bureau, the National Institute of Health, school health organizations, and the Association's Standing Committees on Professional Education, Research and Standards, and Administrative Practice.

offices and laboratory. Salary for man with degree in public health \$7,500 plus 8¢ per mile travel. Write City-County Health Department, Safety Building, Eau Claire, Wis.

Supervising Nurse with certificate in public health nursing. Salary range \$260-\$300. Car furnished. Provision for vacation, sick leave, retirement benefits, permanency. For further particulars write Charles A. Neafie, M.D., Director, Department of Public Health, Pontiac 15, Mich.

Supervisor of Public Health Nurses. Baltimore County Health Department. Urban, suburban, and industrialized areas. Generalized service; director, four supervisors, 36 field nurses. Degree and experience required. Salary \$3,100 to \$3,600; for special preparation in child hygiene, venereal disease, mental hygiene, or orthopedics, \$3,600 to \$3,900. Young public health specialist; recently received Master's degree in Public Health; state university; has had several years' experience as assistant, department of bacteriology, state department of health; for further information, please write Burneice Larson, Director, Palmolive Building, Chicago 11.

Public health nurse; B.S., M.A. degrees, public health nursing; six years, supervisor, state department of health; three years, maternal and child health nursing consultant; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Sanitary engineer; Bachelor of Science in Civil Engineering (major: Sanitary Engineering), Master's in

Public Health Engineering; ten years, director, department of engineering, state department of health; duties include responsibility for entire environmental sanitation in public health engineering program for a population of over million; for additional information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; Ph.D.; six years, health educator nationally known organization; three years, health educator in industry; teaching experience; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health physician; medical degree, eastern university; M.P.H. Johns Hopkins; 17 years' experience in public health field; during war held important assignment abroad; now director of health, city of 100,000; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

WORLD HEALTH ORGANIZATION

"Ever since it was proposed at the San Francisco Conference of 1945 and endorsed by the State Department, this country has taken an active part in the creation of a World Health Organization. We were represented at a preliminary health conference held in Paris in 1946 and later in the same year at the definitive International Health Conference which was held in this city by the representatives of sixty-eight nations and which decided that a World Health Organization was to be established as soon as twenty-six nations had signified their approval. Meanwhile an interim commission, with offices in Geneva and New York, has been demonstrating what such an organization can accomplish, one conspicuous example being the aid rendered in controlling a recent cholera epidemic in Egypt which threatened to involve the whole Near East. Last year the Senate passed a bill which would have made the United States a member of the World Health Organization and which was approved by the House Committee on Foreign Affairs.

"Despite this history, despite the support given to a World Health Organization by the American Public Health Association and virtually every public health authority, the Rules Committee of the House has seen fit to table the Senate's bill. No reason for an action which was taken behind closed doors. Twenty-two nations have already signed the covenant of the World Health Organization, and four more will do likewise in six or eight weeks. This means that an organization will be created, but that the United States will not be a member. The Rules Committee of the House owes the public an explanation.

If it has any good reason for failing to approve the action of the Senate that reason ought to be presented. This country has always been a leader in supporting international efforts to control the spread of disease. At a time when most of continental Europe is undernourished and tuberculosis and other infections are increasing the United States cannot afford to give up that leadership and assume the role of an indifferent observer."—*New York Times*, Mar. 20, 1948.

1948 NORTH CAROLINA WATER WORKS OPERATORS' SCHOOL

The 1948 North Carolina Water Works Operators' School will be held June 7-11 at the University of North Carolina. This school is sponsored by the North Carolina Water Works Operators' Association and the North Carolina Section of the American Water Works Association and is conducted cooperatively by the School of Public Health and the Institute of Government of the university.

Students will be divided into 4 groups according to background, training, and present interest. Instruction will be given in 20 subjects, many of them common to 2 or 3 groups. Not only will technical problems such as filtration, chlorination, corrosion, water quality, hydraulics, and others be discussed but also records, personnel, and legal problems.

As in former years, the school is open both to North Carolina water plant personnel and to residents of neighboring states.

The final schedule of instruction and other information may be secured from Assistant Director, Institute of Government, Chapel Hill, N. C.

THE RETIRING AND INCOMING SURGEONS GENERAL OF THE U. S. PUBLIC HEALTH SERVICE

THOMAS PARRAN, M D, Surgeon General of
the U. S. Public Health Service,
1936-1948

1917-1948, Commissioned Officer in the Regular Corps, U. S. Public Health Service, serving until 1930 in 14 states on public health research and administrative assignments; 1930-1936, Commissioner of Health, New York State; Fellow of the American Public Health Association, and its President in 1937; 1939, winner of the Association's Sedgwick Memorial Medal "for distinguished service in public health"; 1947, winner of the Lasker Award of the Association "for outstanding contributions to the national health and to the World Health Organization"; 1946, Chairman of United Nations International Health Conference in New York City and Chairman of the U. S. delegation.

LEONARD A. SCHEELLE, M D, Surgeon General
of the U. S. Public Health Service,
April 6, 1948

Commissioned Officer in the U. S. Public Health Service, 1934; Health Officer, Queen Anne's County, Md., 1936-1937; Special Fellow, Memorial Hospital, New York, 1937-1939; Officer in Charge of the National Cancer Control Program of the National Cancer Institute, 1939-1942; Assignments with the Public Health Branch, Military Government, U. S. Army, for which he was awarded the Legion of Merit and American Typhus Medal, 1943-1945; Assistant Chief, National Cancer Institute, 1946-1947; Assistant Surgeon General and Director of the Cancer Institute, 1947; Member of the American Public Health Association since 1937.

SECOND N.T.A. RESOLUTION ON LOCAL HEALTH UNITS

The following resolution was passed by the Board of Directors of the National Tuberculosis Association at its meeting on March 19:

The National Tuberculosis Association re-emphasizes its policy that tuberculosis services, to be most effective, should be integrated with general community health facilities and to that end urges its state and local affiliates to work toward the establishment of adequately financed and adequately staffed local health services.

The National Tuberculosis Association endorses the principle enunciated by representatives of 65 national citizens' organizations in a meeting at Princeton, N.J., on September 10, 1947, to the effect that vigorous steps be taken to obtain complete coverage of all states and all communities by local full-time health units under competent professional direction.

The National Tuberculosis Association offers its coöperation to the National Health Council in this program.

The National Tuberculosis Association further endorses in principle the need for federal legislation and assistance to states to complete the coverage of their respective populations and areas with full-time local health units under professional direction.

An earlier resolution of the N.T.A. urged its state and local affiliates to co-operate in developing local official health services as a necessary prerequisite to effective local tuberculosis control activities.

INTERNATIONAL POLIOMYELITIS CONFERENCE

The First International Conference on Poliomyelitis in New York City, July 12-17, was announced briefly in the February *Journal* (p. 252).

More detailed plans are now available. Ten world medical and research authorities on poliomyelitis have been named presiding officers for the plenary sessions. These presiding officers and subjects include:

Oswaldo P. Campos, Clinical Orthopedic Surgeon, Hospital Jesus, Rio de Janeiro, Brazil, "The Importance of Poliomyelitis as a

World Problem"; Rustin McIntosh, Professor of Pediatrics, Columbia University, "Poliomyelitis: The Early Stage"; Robert Kno-Song Lim, Surgeon General, National Defense Medical Center, Shanghai, China, "The Management of Poliomyelitis: The Early Stage"; Arthur Steindler, Professor of Orthopedic Surgery, State University of Iowa, "Poliomyelitis: The Convalescent Stage"; Arvid Wallgren, Professor of Pediatrics, Royal Caroline Medical Institute, Stockholm, Sweden, "The Management of Poliomyelitis: The Convalescent Stage"; Carlos S. Ottolenghi, Docente Libre de Ortopedia, Buenos Aires, Argentina, "The Management of Poliomyelitis: The Late Stage"; James E. Paullin, Professor of Clinical Medicine, Emory University, "Bulbar Poliomyelitis"; Pierre L. LePine, Director of Laboratories, Pasteur Institute, Paris, "Immunology and Chemotherapy in Poliomyelitis"; Harry S. Mustard, Commissioner of Health, New York City, "The Public Health Aspects of Epidemic Poliomyelitis"; and Thomas Parran, Surgeon General, U. S. Public Health Service, "Poliomyelitis Throughout the World."

The Conference is being held under the auspices of the National Foundation for Infantile Paralysis with the coöperation of 23 United States government agencies and scientific societies, among them the American Public Health Association.

Conference headquarters have been set up in the Waldorf Astoria Hotel, New York City.

INSECT CONTROL IN RETROSPECT

This announcement will be too late to be of any great benefit to health workers in the field. However, it may tend to indicate trends which are taking place in insect control activities. Within almost a week, notices were received of two conferences for pest control operators; the first, that of the New York State Pest Control Association held at Cornell University, March 29-30, and second, that of the 12th Annual Purdue Pest Control Operators Conference held at Purdue University, April 5-9. Anyone who may be interested in programs or methods of organization should write

to Charles E. Palm, Entomology Department, Cornell University, Ithaca, N. Y., for the former, and to Professor J. J. Davis, Agricultural Hall, Purdue University, Lafayette, Ind., for the latter.

WATER EMERGENCY PUBLICITY MATERIAL

The Mathieson Alkali Works has prepared and distributed to state health officers in areas likely to be affected, a packet of material designed to advise the public of necessary emergency health measures in the event of floods. Included in the packet are releases for use in newspapers before, during, and after a flood. There are similar releases for radio broadcasts and a bulletin for posting in public places. Also included are recommendations concerning typhoid inoculations, treatment of water for drinking and cooking purposes, handling of contaminated food and food containers, disinfecting wells in flood areas, and clean-up of buildings after floods. A list of distributors handling chemicals which might be in demand during flood emergencies is also contained in the packet. For further information, write to Mathieson Alkali Works, Inc., 60 East 42 Street, New York 17, N. Y.

NEW ENGLAND MEETING

The annual Massachusetts Public Health Conference and the New England Health Institute will be held at the University of Massachusetts, at Amherst from June 16 to 18, 1948. Among the speakers at this three day session are:

Martha M. Eliot, M.D., President, A.P.H.A.
Leonard A. Scheele, M.D., Surgeon-General,
U.S.P.H.S.

Ira V. Hiscock, Sc.D., Professor of Public Health, Yale University

Hugh R. Leavell, M.D., Professor of Public Health Practice, Harvard University

V. A. Van Volkenburgh, M.D., Assistant Commissioner, New York State Department of Health

Charles F. Wilinsky, M.D., President-Elect A.P.H.A., will preside, and the New England state health commissioners will participate.

All members of the A.P.H.A. are invited and ample dormitory accommodations are available for all who wish to attend.

HEARING ON LOCAL HEALTH SERVICES BILL

The Committee on Interstate and Foreign Commerce of the House of Representatives held a hearing on the Local Health Services Bill (H.R. 5644 and 5678) on April 8. Five members of the committee were present and heard testimony in favor of the bill from Mrs. L. W. Hughes, President of the National Congress of Parents and Teachers, James R. Miller, M.D., member of the Board of Trustees of the American Medical Association, Vlado A. Getting, M.D., President of the State and Territorial Health Officers Association and Haven Emerson, M.D.

The only opposing testimony, based on a fear of further federal centralization, was given by H. B. Anderson, Secretary of the Citizen's Medical Reference Bureau. He testified that he represented a membership of 1,000 members who had not previously been consulted, but would approve his action at a later date.

No hearing has yet been held on the identical Senate bill providing for federal grants-in-aid to state health departments earmarked specifically for the development of local health units on the basis of an overall state plan. The Chairman of the Senate Subcommittee on Health of the Committee on Labor and Welfare is Senator H. Alexander Smith of New Jersey.

PREVENTIVE MEDICINE TO THE FORE

At the Health and Family Life Symposium of the Community Service Society of New York, on March 18, Bailey

B. Burritt, the retired Director of the Society and Executive Director of the National Health Council, announced a project for the study of 200 families who live in one of New York City's neighborhoods to learn "what preventive and health maintenance services would be effective and practical." This service would utilize many of the techniques learned by the Peckham experiment in England. This experiment and its results were discussed at the same meeting by Dr. Innes Pearse, medical director.

Among other current activities, in exploring the possibilities of preventive medicine, is the University of Minnesota's project whereby 300 St. Paul and Minnesota volunteers in the prime of life are being examined periodically for 10 years by clinicians in order chiefly to note the factors that account for high blood pressure and for hardening of the arteries.

In New York City, the Health Commissioner, Harry S. Mustard, M.D., has appointed C. Ward Crampton, M.D., Chairman of an advisory committee on geriatrics. New York State has a joint legislative commission on problems of aging.

GRADUATE FELLOWSHIPS IN COMMUNITY NUTRITION AT THE UNIVERSITY OF TENNESSEE

The College of Home Economics of the University of Tennessee offers several one year graduate fellowships in Community Nutrition of \$1,200 and free tuition. The program, leading to the degree of Master of Science in Community Nutrition, includes three-quarters of work in residence at the university and one-quarter of supervised field work in a health agency. Candidates are trained for positions as nutritionists with health and welfare agencies.

Academic requirement for admission is a baccalaureate degree in home economics with a major in foods and nutrition, or its equivalent. Two years of

experience such as teaching, extension work, Farmers Home Agency work, hospital, or other food service or equivalent, are required. Interests and ability of the candidate are considered in accepting students for training.

Application blanks and further information may be obtained from the College of Home Economics, University of Tennessee, Knoxville.

FIRST NATIONAL SANITATION CLINIC

The first National Sanitation Clinic will be held at the University of Michigan, June 21-25 with the coöperation of the National Sanitation Foundation. Approximately 250 participants will divide themselves into 12 clinic groups for intensive deliberations on as many subjects related to food sanitation. In general each group will include 6 representatives from public health and 6 from industry, 2 co-chairmen, and from 2 to 5 consultants.

The stated purpose of the clinic is to discuss various phases of environmental sanitation control—with particular reference to foods—in an effort to arrive at a statement of principles, methods of procedure, equipment, etc., that are acceptable to public health officials and to industry. It is hoped that the agreements reached in this group may be approved by both public health officials and industry as reasonable goals and guides in food sanitation.

DR. HILLEBOE MAKES TRIP TO EUROPE

Herman E. Hilleboe, M. D., New York State Commissioner of Health, spent the last half of February on a trip to Europe, going first to Geneva, Switzerland, where he represented the United States in a four day discussion of world-wide tuberculosis control with members of the Expert Committee on Tuberculosis of the Interim Commission of the World Health Organization.

In addition, Dr. Hilleboe had a one day conference on tuberculosis control

with Rome public health physicians, made a three day study in Athens of the mass BCG vaccination program now in progress in Greece, and examined the research work currently being conducted by the State Serum Institute of Denmark in Copenhagen. There a coöperative research project was formulated to be carried on by the Serum Institute and the New York State Health Department's Division of Laboratories and Research.

TEXAS PUBLIC HEALTH ASSOCIATION

The Texas Public Health Association held its Annual Meeting in Houston February 22-25. This meeting was the largest ever held, with a total attendance of 575.

The out-of-state speakers included Pearl McIver, R.N., Martin A. Frobisher, Jr., D.Sc., Charles B. Frasher of the A.P.H.A. Merit System Service, Albert E. Bailey, Ph.D., James A. Doull, M.D., and Ira V. Hiscock, Sc.D., who led a panel on Public Health Administrative Practices.

The new officers of the Texas society are:

President—Austin E. Hill, M.D.

President-elect—W. R. Ross, M.D.

1st Vice-President—B. A. Young

2nd Vice-President—Belle Blackwell, R.N.

Executive Secretary—Earle W. Sudderth

A.P.H.A. UNDERTAKES STATE STUDY IN PENNSYLVANIA

Norris W. Vaux, M.D., Secretary of Health for Pennsylvania, has recently announced a survey of public health activities of Pennsylvania by the Committee on Administrative Practice of the American Public Health Association.

In commenting on this study, Dr. Vaux said:

The Pennsylvania Department of Health has had a long and honorable history. Its activities through the years have expanded with increasing knowledge in the techniques of preventive medicine and in the control of disease.

This expansion has been so rapid and diverse that there has been little opportunity to pause

and take stock, an essential practice for every organization that wants to know its present status and what future direction it should take.

With this thought in mind, Governor Duff, and I, believe that a thoroughgoing evaluation of the Commonwealth's public health administration which will measure structure and activities against currently accepted public health procedures and practice will be of value in strengthening the resources of the Department and in assuring it of an administrative structure soundly conceived and adequately operated.

With the Governor's approval, therefore, the Department of Health has requested the American Public Health Association through its Committee on Administrative Practice, which has conducted many local health studies, to survey the public health activities of Pennsylvania.

Important among the aspects of this survey will be the efficiency, extent, and effectiveness of (1) the state Department of Health; (2) local health services to communities; and (3) the relationship of the state voluntary health agencies to the state and local health services.

A representative committee of public minded and influential citizens, now being appointed by Governor Duff, will serve in an advisory capacity and Dr. Vaux has expressed the hope that this committee will be an effective instrument for implementing the survey's recommendations.

N.T.A. POLICY ON BCG VACCINATION

The Executive Committee of the American Trudeau Society, the medical section of the National Tuberculosis Association, recently adopted a statement of policy with respect to BCG vaccination against tuberculosis. Because such vaccination does not provide complete protection against tuberculosis its use for the general population is not recommended until further controlled studies are conducted.

The Society's recommended policy is for BCG vaccination of members of groups constantly exposed to tuberculosis if they have a negative reaction to the tuberculin test. The person with a positive reaction, indicating that he has had a primary tuberculosis infection

and his body has built up a degree of acquired immunity, probably does not benefit from BCG vaccination. For the present, therefore, BCG vaccination is recommended for doctors, medical students and nurses, hospital and laboratory personnel in contact with the tuberculosis bacillus, individuals unavoidably exposed to tuberculosis in the home, and patients and employees of mental hospitals, prisons, and other custodial institutions.

The Society warns against placing complete reliance on BCG even for these groups and points out that proper precautions should be taken to minimize or prevent "undue hazardous exposure of hospital patients and personnel and members of a household if an infectious patient is under treatment in the home."

PERSONNEL AND SERVICES OF LOCAL HEALTH UNITS

The U. S. Public Health Service through the Records and Reports Unit of the Bureau of State Services has just published a report of public health resources in local full-time health jurisdictions, including state districts. The number of personnel in 4 categories is analyzed according to whether they meet the minimum standards set up by the Subcommittee on Local Health Units in its report, *Local Health Units for the Nation*.

The report also gives detailed information on public health clinic service available in local jurisdictions receiving federal-state financial aid.

The report, prepared by Evelyn Flook and Arthur P. Gill, is available from the Bureau of State Services, U. S. Public Health Service, Washington 25, D. C.

FIELD TRAINING IN PUBLIC HEALTH ENGINEERING

The Michigan Department of Health announces summer field training opportunities to individuals desiring experience in public health engineering work.

The program will be similar to one conducted by the department last year.

Graduates or undergraduates of recognized professional schools with training in one of the branches of public health (engineering, dairy science, food technology, bacteriology, etc.) will be accepted. Undergraduates must have completed their junior year of study. Assignments will be to county health departments with special facilities for the training. Stipends of \$150 per month will be paid each candidate by the W. K. Kellogg Foundation. Veterans are entitled to the federal subsistence allowance while in training. Work will start about June 14 and continue to the middle of September.

Additional information can be obtained from John M. Hepler, Director, Bureau of Engineering, Michigan Department of Health, Lansing.

MARKLE FOUNDATION MEDICAL SCHOLARS

With the avowed purpose of relieving the current shortage of scientists equipped to carry on and teach research, the John and Mary R. Markle Foundation of New York recently announced a "Scholars in Medical Science" program. A total of \$400,000 has been allocated to support, for a 5 year period, 16 doctors carrying on research in a variety of medical subjects in 16 different universities.

100 YEARS OF A.A.A.S.

Planning has begun for the centenary celebration of the founding of the American Association for the Advancement of Science. Chairman of the Centennial Policy Committee is Dr. Harlow Shapley, Director of the Harvard Observatory. The keynote of the meeting, to be held in Washington, D. C., September 13-17, is "One World of Science." Preliminary plans call for technical symposia, 4 or 5 concurrently each morning, for free afternoons to visit the scientific and cultural institutions of Washington,

and for non-technical broad surveys of current progress in important fields of science for the evenings.

NATIONAL HEART INSTITUTE PROPOSED BY SENATE BILL

On February 25, Senators Ives, Bridges, Murray, and Pepper introduced the bi-partisan bill S2215, which would establish a National Heart Institute under the U. S. Public Health Service. It would provide greatly increased federal support of research in and control of cardiovascular diseases. The bill differs only slightly from the Keefe and Smathers bills introduced in the House in January.

U. S. PUBLIC HEALTH SERVICE 1949 BUDGET

The Washington Report on the Medical Sciences, a weekly newsletter concerning medical and public health matters, reports liberal grants to the U. S. Public Health Service by recent action of the House Appropriations Committee. The overall 1949 budget approved for the Service was \$173,230,500, an increase of 30 per cent over the previous year. Seventeen million dollars was approved for venereal disease control. Because the committee was impressed with the BCG studies conducted by the Public Health Service, over 9 million dollars was appropriated for tuberculosis control, two-thirds of which is for grants-in-aid to state and local health departments.

The National Institute of Health was granted its full request of \$13,570,000, plus an additional \$100,000 for peptic ulcer research. More than half of the institute's appropriation is for research grants to hospitals, clinics, universities, and other organizations.

The Institute's funds for cardiovascular studies were increased from half a million in 1948 to \$1,382,500 in the 1949 appropriation of the House. The cancer appropriation of \$14,000,000

was renewed plus an additional \$8,000,000 recommended for grants-in-aid for planning, land acquisition, and building of research centers.

A new item of a million and a half dollars was recommended for nation-wide demonstrations in schools of the effectiveness of sodium fluoride in preventing tooth decay.

PERSONALS

Central States

C. A. ABELE, formerly Director of the Country Dairy Inspection Section of the Chicago Health Department since 1940, has recently become Director of Public Health Research of the Diverssey Corporation, also of Chicago. Mr. Abele organized and served for 20 years, the Bureau of Inspection for the Alabama State Department of Health. He is a referee on the Committee on Standard Methods for Dairy Products, A.P.H.A.

CORINNE EDDY, M.D.,† was appointed Health Officer for the DeWitt-Piatt County (Illinois) Health Department with offices in Clinton on January 1. Dr. Eddy was formerly Director of the City-County Health Department, Lincoln, Neb.

DONALD M. HARRIS, M.D.,* became Health Officer of the newly organized full-time Health Department of Gary, Ind., on February 1. According to the *Monthly Bulletin* of the Indiana State Board of Health he is "the first formally trained full-time health officer (local) in Indiana." He had previously served in local health units in Iowa, Michigan, and Nebraska.

J. P. OWENS, M.D., has been named to succeed E. H. SCHOENLING, M.D., as Hamilton County, Ohio, Health Commissioner. Dr. Owens has been a practising physician in Cincinnati chiefly interested in industrial medicine.

Eastern States

WENDELL R. AMES, M.D.,* former Health Commissioner of the Cattaraugus County, N. Y., Health Department, has been appointed Deputy Health Commissioner for Preventable Diseases, including tuberculosis control of the new Buffalo City-Erie County Health Department.

CHARLES S. CAMERON, M.D., recently a corps member of the U. S. Naval Medical Corps, has been appointed Medical Director of the American Cancer Society, New York, N. Y. Dr. Cameron is a Fellow of the American College of Surgeons.

J. ELLIOTT HALE,† formerly Director of the Industrial Hygiene Division of the Bureau of Health, Maine State Department of Health and Welfare, has taken up new duties as Superintendent of the Kennebec, Me., Water District.

GEORGE E. LAUBACH, licensed Health Officer in New Jersey, became Health Officer of the City of Elizabeth on January 15. He had previously been Health Officer of Dover.

EARL LUDLAM, D.D.S., has succeeded J. M. WISAN, D.D.S.,* as Chief of the Division of Dental Hygiene of the New Jersey State Health Department. He has been Assistant Director of the division for the past 10 years. Dr. Wisan resigned to become Director of the Division of Health Education of the American Dental Association whose headquarters are in Chicago, Ill.

CLINTON P. MCCORD, M.D., of Albany, N. Y., has been appointed as Consultant in Psychosomatic Medicine in the New York State Department of Health, preparatory to the launching of a state-wide educational program related to emotional factors in disease. Dr. McCord has been practis-

ing neuro-psychiatry and analytic psychiatry for the past 35 years and is a Diplomate of the American Board of Neurology and Psychiatry and Consultant to the Albany Society for Advancement of Psychosomatic Medicine.

WILLYS M. MONROE, M.D.,† will become Health Officer of Greenwich, Conn., on July 1. He has been Health Commissioner of Pittsfield, Mass., since 1923 and served in both world wars, returning from recent military service with the rank of lieutenant colonel.

PHILIP S. PLATT,* Director of Lighthouse of the New York Association for the Blind spoke on voluntary health agencies at the annual meeting on April 15 of the Hartford, Conn., Tuberculosis and Public Health Society.

WILLIAM REINER-DEUTSCH, M.D.,† Director of Industrial Testing Laboratories and Technical Director of the National Brewers' Academy and Consulting Bureau, New York, N. Y. has been elected corresponding member of the Société de Biologie de France.

ELIZABETH P. RICE, formerly clinical professor of the social aspects of medicine at the Yale School of Medicine, New Haven, Conn., and assistant professor of the social aspects of nursing at the Yale School of Nursing, has been appointed the first Social Service Worker to the Faculty of the Harvard School of Public Health, Boston, Mass., as part of a new program to study the role of family life in the health of children. Miss Rice will commence a study of the preventive aspects of social work.

HELEN E. WEAVER, R.N.,† has been appointed as Consultant in Nursing Activities, the National Society for the Prevention of Blindness, New York, N. Y. Miss Weaver was formerly Consultant Public Health Nurse of the Division of Venereal Disease Con-

* Fellow A.P.H.A.

† Member A.P.H.A.

trol, New York State Department of Health, Albany.

SIDNEY I. WOLFSON,[†] has resigned as assistant to the District State Health Office, Freehold, N. J., to become Health Officer of Dover.

MARGARET POND ZEALAND was appointed nutritionist of the New Jersey State Health Department in February. Mrs. Zealand formerly served as dietitian in several hospitals in New York City.

Southern States

HAROLD V. DARNELL, B.Sc., has been appointed as assistant to ROBERT P. FISCHER, M.D.,* Secretary of the American Pharmaceutical Association, Washington, D. C. Mr. Darnell has been Executive Secretary of the Indiana Pharmaceutical Association since 1939.

ESTHER M. FINLEY,* Senior Assistant Nurse Officer of the U. S. Public Health Service, Washington, D. C., has been appointed Director of the Public Health Nursing Program for the Kanawha-Charleston Health Department, W. Va.

JOSEF JORDAN WEISSKOPF, M.D.,[†] recently appointed Surgeon in the Reserve of the U. S. Public Health Service, was called to active duty as of April 30. Since January, 1945, he has been Chief, Planning Branch, Medical and Sanitation Supplies Division, UNRRA.

Western States

NEW MEMBERS OF THE FACULTY AT THE SCHOOL OF PUBLIC HEALTH, UNIVERSITY OF CALIFORNIA, SAN FRANCISCO, ARE:

JACOB YERUSHALMY, Ph.D.,* as Professor of Biostatistics. Dr. Yerushalmy was formerly Principal Statistician, Division of Tuberculosis, U. S. Public Health Service. He recently

returned from Denmark where he served as Consultant in the tuberculosis control program.

EDWIN H. LENNETTE, M.D., Ph.D., who recently became the director of the Virus Laboratory, California Department of Public Health, has also been appointed Lecturer in Public Health. Dr. Lennette was a member of the Field Staff of the International Health Division of the Rockefeller Foundation until 1946 when he became Chief of the Medical Veterinary Division of the War Department.

DAVID FROST, M.D.,[†] became the first full-time Health officer of the City of Alameda, Calif., in February, 1948. He was formerly Chief of Venereal Disease Control in the Oakland Health Department.

Other Areas

ROBERT H. MARKS, M.D.,[†] Chief of the Tuberculosis Bureau of the Hawaii Territorial Department of Health, has announced his resignation, effective February 26. He returns to the mainland as Medical Director of Jefferson Sanatorium, Birmingham, Ala.

LUIS M. MORALES, M.D., former President of the Medical Association of Puerto Rico, was elected a member of the Council of the National Committee on Mental Hygiene at the organization's recent annual meeting in New York.

Deaths

EDWARD THOMAS DEVINE, Ph.D., known in social work and reforms, died in Chicago on February 27, at the age of 80.

HAROLD GILBERT MCGEE,* Charter Fellow of the Engineering Section of the Association, and Director of the Municipal Research Bureau of the Akron Chamber of Commerce since 1923, died at his home in Hudson, Ohio, on February 13. Besides being a tax and

* Fellow A.P.H.A.

† Member A.P.H.A.

finance expert in his early career he had also been Sanitary Engineer in the Michigan State and Jackson City Board of Health, and in the Ohio State and Lucas County boards. He was the author of numerous articles in engineering and public health journals as well as reports on municipal, school, county, and state budgets.

CONFERENCES AND DATES

- American Association for the Advancement of Science. Centennial Meeting. Washington, D. C. September 13-17.
- American Congress of Physical Medicine. Hotel Statler. Washington, D. C. September 7-11.
- American Dairy Science Association. University of Georgia, Athens, Ga. June 14-16.
- American Dental Association. Chicago, Ill. Week of September 12.
- American Dietetic Association. Boston, Mass. October 18-22.
- American Hearing Society. National Conference and Annual Meeting. Pittsburgh, Pa. May 19-23.
- American Home Economics Association. 39th Annual Meeting. Minneapolis, Minn. June 21-24.
- American Hospital Association. 50th Anniversary Convention. Atlantic City, N. J. September 20-24.
- American Library Association. Atlantic City, N. J. June 13-19.
- American Occupational Therapy Association. Hotel Pennsylvania, New York, N. Y. Sept. 7-11.
- American Public Health Association—76th Annual Meeting. Boston, Mass. November 8-12.
- American Public Works Association. Boston, Mass. October 17-20.
- American Red Cross. San Francisco, Calif. June 20-24.
- American Society for the Study of Sterility. Fourth Annual National Session. Chicago, Ill. June 21-22.
- American Society of Planning Officials. New York, N. Y. October 11-13.

**ECONOMICAL
SANITIZATION
of MILK UTENSILS**

with the

B-K
REG. U. S. PAT. OFF.
PLAN

You won't find a sanitation program today that is much simpler than the B-K Plan... at such low cost. You will get results with it, if you follow the easy directions. But remember—no system can produce these results without a certain amount of cleaning and good old fashioned elbow grease.

The B-K Plan stresses, after use, first the rinsing of utensils and equipment in cold water and then the scrubbing in hot water containing soapless General Manual Kleanser. Before milking, rinse milking machines, and utensils, and wipe cow's udder and teats with efficient, inexpensive B-K solution. These simple steps have helped many average-size farms get surprisingly low counts.

B-K* Chlorine-Bearing Powder contains 50% available chlorine. It speedily sanitizes dairy utensils and reduces the number of bacteria that result in poor quality... thermodurics and others. General Manual Kleanser loosens milk solids and really cleans.

Farm operating costs remain high... and past experience shows that milk prices are sometimes reduced without a proportionate lowering of costs. Recommend the simple, economical B-K Plan and you will help both farmer and city milk supply.

Literature explaining the role of bacteria in milk and their control is available for farmers. Programs of education also on request. Send for them—by writing to B-K Division, Pennsylvania Salt Manufacturing Company, 1000 Widener Building, Philadelphia 7, Pa.

The Role of **IODINE** *in Clinical Diagnosis*

- Diagnosis is the art or scientific process by which a disease is recognized. Success or failure in establishing a correct diagnosis depends in large measure on the use of reliable, safe and efficient clinical and laboratory procedures.
- Iodine compounds occupy a unique position as indispensable aids in providing X-ray evidence that is informative and most frequently complete. They supply the ideal contrast media for many diagnostic procedures—including bronchography, cholecystography, pyelography and myelography. Without these compounds, an accurate diagnosis might be difficult or impossible to make.
- Likewise in the fields of prevention and therapy, few medicaments serve such useful and varied purposes as Iodine with its many compounds and derivatives.

Air Pollution*

Engineering Section

SINCE the field that might be considered by this committee is large, it was believed advisable to restrict the scope of this year's report to one phase of the air pollution problem; namely, atmospheric pollution. The report does not include air pollution in enclosed spaces except as they may affect the outside atmosphere. It also seemed advisable in this initial report to limit its scope to certain available information on the source, character, and effect of atmospheric pollution and to some information on the methods of control.

Broadly speaking, atmospheric pollutants include smoke, dust, gases, vapors, fumes, and mists that may be present in the air and that create a nuisance, adversely affect animal or plant life, or cause property loss or damage.

Smoke and dust are no doubt the most widely recognized atmospheric contaminants. Investigation of atmospheric pollution in many cities, including the fourteen large cities in the United States surveyed¹ by the U. S. Public Health Service (1931-1933), have recorded the conditions that exist in some urban communities in the United

States and have brought out certain fundamental relations that are of importance in organizing and carrying out smoke and dust abatement programs.

Ely² has pointed out that "the so-called smoke abatement problem divides itself into two parts, the smoke problem and the dust problem. The smoke problem, i.e., smoke stacks, is one of combustion and it is always possible with proper equipment and design to stop a smoking stack. The other problem, that of dust and dirt, is a matter of air pollution, and its solution depends on many factors." It should be realized that the smoke stack, even when not smoking, may be the source of fly ash and dust, particularly in the case of pulverized coal furnaces with ineffective fly ash catchers.

In reference to dustfall due to substances other than smoke, the Chicago Association of Commerce in a report on air pollution points out the importance of "refuse in alleys, dust in the streets and vacant lots, dirt on rooftops, and material from tires, clothing, shoes, buildings and all other things that 'wear' as a result of busy city life. At times even soil from farms hundreds of miles away is important." Another form of dust particle that should not be overlooked is the pollen which, in certain concen-

* Report of the Committee
COMMITTEE ON AIR POLLUTION
Organized 1946.

trations, is responsible for allergic reactions in susceptible individuals.

To these more common forms of smoke and dusts, present to some extent in the air of practically every community, must be added the gases, fumes, vapors, and mists, originating particularly from industrial establishments, that are present in some communities as atmospheric contaminants in sufficient concentration to produce a nuisance, cause property loss, and in some cases affect the public health.

While the presence in the atmosphere of any of the contaminants mentioned may conceivably have health implications, it has always been difficult, and in many instances impossible to demonstrate actual damage to health.

Stead³ has included in the industrial contaminants that cause nuisances: (a) inert smokes and dusts, (b) mucous membrane irritants, and (c) malodorous substances.

Smokes that result from the combustion of fuel contain soot, fly ash, and unburned or partially burned fuel. Smoke alone, for example, in excessive quantities is disagreeable, discomforting, and of economic significance, but the evidence so far collected has not been able to establish a definite relationship between smoke and health.

The discharge into the atmosphere of dusts from industries such as smelters, cement plants, rock crushers, sand blast plants, and roofing plants, and of some of the organic dusts may, however, have health implications.

Mucous membrane irritants emitted from industrial plants include respiratory irritants such as sulfur dioxide, chlorine, and phosgene, and eye irritants such as acrolein, butadiene, chloroform, and hydrogen sulfide. The discharge of irritating gases into the atmosphere in objectionable quantities will naturally cause serious complaints.

Malodorous substances may originate from a variety of industries and other

sources including rendering plants, tanneries, soap factories, glue plants, oil refineries, sewage disposal plants, internal combustion engines, etc. Stern⁴ points out that "the chemical groups most frequently responsible for unpleasant odors are the sulfides, disulfides, mercaptans, thiocyanates, isocyanides, compounds analogous to the foregoing of selenium or tellurium, and aldehydes" and that "many of these substances are recognizable as malodorous at less than 0.1 p.p.m., some at as low as 0.0000001 p.p.m."

Various methods and techniques have been devised for locating and studying the source, distribution, and effect of atmospheric pollution. Unless the source and distribution of the contaminant can be determined by direct observation, the discovery of the origin of atmospheric contaminants may be a difficult one requiring the exercise of highly specialized technical skills. The "Report Submitted to the Trail Smelter Arbitral Tribunal," *Bulletin 453*, U. S. Bureau of Mines,⁵ is an illustration of the exhaustive technical investigation that may be necessary to determine the damage resulting from the discharge of SO_2 from a smelter under the meteorological conditions that existed in the area surrounding this plant.

A number of devices such as electrostatic and thermal precipitators, impinging apparatus, filters, and atomizers, have been developed for the sampling of dust and bacteria in air. These devices are described in various publications. Probably the most common measure of smoke density is the Ringelmann⁶ chart, which is used as a guide in the enforcement of many smoke ordinances.

To establish proof as to the distribution from a given source of such common substances as smoke or fly ash, a number of methods have been used or suggested. One method consists of adding radioactive salts to the smoke

stream in a stack and recovering the radioactive components in the area under observation. Another method described by Sinatt⁷ is the identification of cenospheres, which are hollow spheres that are produced when certain solid fuels are burned at temperatures above 600° F. in a limited air supply. If deposits of these cenospheres are recovered from the area of complaint, they constitute evidence of the source of the trouble.

An indirect effect of smoke and dust is the diminution of sunlight and the increase in fogs, clouds, and haze. Fogs accentuated by smoke and dust add to certain hazards associated with motor and airplane transportation. This hazard has been considered in connection with the location of some important airports in this country. Studies have been reported by Drinker⁸ on methods for eliminating fogs at airplane landings, but these have apparently not yet reached a practical stage.

The health hazards associated with the release of radioactive substances into the atmosphere have aroused world-wide interest. In times of peace some of the actual and potential sources of these radioactive atmospheric contaminants are plants producing plutonium, uranium, and radioisotopes, and possibly to some extent laboratories conducting experiments with radioactive substances. Studies⁹ have been made on the possibilities of the release of radioactive dusts and gases from atomic energy plants, and progress has been made in developing methods for health protection against atmospheric contamination from such plants. Much information on this subject is not yet released for publication.

The control of pollens responsible for allergic reactions in certain individuals has been given more attention in the past few years. Various methods have been tried to control hay fever pollen-producing plants, including cutting the

plants before they blossom, and chemical treatment. Among the chemicals recently used for the destruction of these plants, especially ragweed, which is a most important member of the hay fever producing group, is dichlorophenoxyacetic acid commonly known as 2,4-D. This is a synthetic plant hormone which disturbs plant growth and eventually destroys the plant. The chemical is usually applied in the form of a spray but may be dusted. A large number of communities are reported to have used 2,4-D, among them the City of New York.

Sol Pincus has made the following brief statement for this report concerning the use of 2,4-D by the New York City Health Department:

In 1946, it was estimated that 10,000 acres were infested with ragweed in the five boroughs. It was decided that the use of the new chemical, 2,4-D, dichlorophenoxyacetic acid, would be the most economical method to control ragweed in New York City. Starting very late in the season, we were able to control the growth of 3,000 acres of ragweed, which contributed probably to the unusually low atmospheric pollen concentration during the ragweed season. It was a coöperative program. Equipment and personnel were contributed by the coöperating departments with the Health Department coördinating the work, furnishing the technical direction, chemicals and supplies.

At the close of the 1946 season, a survey was conducted by the Police Department which resulted in 85 Precinct maps showing the locations and areas of ragweed growth in the city. These maps served as guides in the preparation of plans for the 1947 campaign.

It was estimated that 8,000 acres had to be treated in 1947. We obtained six high-pressure power spraying units from the War Assets Administration, two skid-mounted decontaminating units from the U. S. Public Health Service, and various supplementary equipment from the War Assets Administration.

Public and private vacant properties were treated alike without making a charge to the private owners. During the 1947 season, it is estimated that approximately 4,000 or 4,500

acres will be sprayed. It has been adjudged that one application of the chemical is sufficient to kill the ragweed or prevent the pollination and seed production.

A spray solution containing 1,000 p.p.m. of 2,4-D was used. This was applied at the rate of approximately 300 gal. per acre. The sodium and ammonium salts of 2,4-D were used. The cost of the chemical was approximately \$1.25 per lb., and the cost for the area sprayed including labor and use of equipment and chemicals, was approximately \$11.00 per acre, in 1946. Figures for 1947 are not yet available.

It was noted that the area sprayed during July and August of 1946 showed very little or no growth of ragweed during the 1947 season.

Many neighboring communities have instituted similar programs in reduction of ragweed pollen. This department cooperated in making available our experiences and also in giving a training course under New York University direction to health officers and other officials of these communities.

While encouraging results have been obtained in the elimination of hay fever pollen-producing plants in certain areas where regulatory measures are in effect, the control of pollens from outside areas still remains a problem. Investigations have shown the long distance that pollens may travel under meteorological conditions favorable to their migration. The question, however, of the kind and the concentration of hay fever-producing pollens, regardless of their source, becomes an important factor in dealing with any situation.

Various methods have been developed for sampling and counting air-borne pollen and for computing the results of such examinations in terms of pollen concentrations in the atmosphere. Dahl and Ellis,¹⁰ after a study of the methods for computing pollen concentrations state that "those which utilize volumetric factors derived from Stokes' law are less accurate than those methods which employ a unit area basis," and that "it is to be desired that reports should include a record of the amount of pollen per unit of area of the exposed

slide, whether volumetric data are computed or not."

The measurement of gases and vapors emitted from various sources presents serious difficulty when low concentrations are encountered, because the lower limit of most chemical methods is around 1 p.p.m. by volume. Some instruments, however, have been developed that are helpful in this connection. The Thomas Autometer¹¹ is one apparatus which will collect its own samples and measure and record concentrations of sulfur dioxide and sulfur trioxide as low as 2 parts per billion. This machine has also been developed to measure separately the concentration of other gases, including hydrogen sulfide, carbon disulfide, ethyl mercaptan, and thiophene. The method, at a higher operating temperature, is also applicable to chloroform, carbon tetrachloride, ethylene chloride and chlorobenzene.

Whipple¹² in 1921 pointed out many of the fundamentals in regard to odors and their relationship to odor nuisances in a discussion on odors and their travel habits.

The measurement of odors from various sources is attended by many difficulties. Various methods^{4, 13-15} that employ the sense of smell of the observer have been devised for evaluating the intensity of odors. Odor scales^{4, 16} indicating threshold odor concentrations and tables showing the concentrations and characteristics of various readily perceptible substances in air have been prepared.

Hemeon and Hatch¹⁷ point out that "osmometry is in need of research cultivation; we know little about it. Moreover, the subject of odors is inextricably entangled with psychological factors which although usually foreign to chemist and engineer cannot be ignored. The facts of olfactory fatigue and revivification by periodic variation in concentration are relevant, as is the

law expressing the logarithmic relation between sensory response and the magnitude of stimulus—i.e., concentration of the vapor or gas.”

The instrumental measurement of odors presents a difficult problem, however, because odors are due to the perception of molecules rather than a response to conditions. Some attempts have been made to develop physical methods of measurement, such as the work of Dyson,¹⁸ who used the Raman shift for this purpose. Apparently, however, no practical method has so far been devised, and there is need for research in this field.

A large amount of technical work has been undertaken on methods to prevent atmospheric pollution from smoke, dust, gases, vapors, and fumes.

Probably the greatest amount of attention has been focused on smoke control, since this kind of air pollution is obvious and attracts public attention. Fuels and combustion equipment and methods have been studied. As a result detailed information is available on the construction and operation of nearly all types of fuel burners to improve or correct combustion difficulties.

Extensive studies have been made on the polluting substances released from stacks and the dilution that may be anticipated under varying meteorological and other environmental conditions. Investigations of the U. S. Bureau of Mines¹⁹ indicate that factors of dilution of the polluting material at given points of travel can be computed with rough accuracy for a given horizontal distance if the stack velocity and wind velocity are known.

The importance of meteorological and other environmental studies should not be overlooked in selecting new plant sites, especially where gaseous waste disposal problems are anticipated.

Meteorological factors are involved both in the creation and in the solution of atmospheric pollution problems. For

example, there are the disturbing effects of temperature inversion, which cause a natural rise of atmosphere containing contaminants when the earth's surface is warmer than the air, but produce the formation of a so-called “lid,” holding pollution down near the earth's surface, when the earth is colder than the air.

The control of industrial dusts, gases, vapors, and fumes at the source also presents difficult technical problems. However, considerable progress has been made in their solution. Hemeon and Hatch¹⁷ mention among the available control methods the following: “scrubbing and absorption towers for vapors and gases, especially acid gases, various types of dust and fume collectors, and miscellaneous chemical processes such as combustion of organic contaminants or neutralization in conjunction with scrubbing.” In some cases the use of raw materials free from objectionable impurities may eliminate the difficulties, while in others the utilization of the contaminant in the manufacture of a useful by-product may provide a solution. These authors mention the substantial body of experience in gas cleaning in industry, much of which has not been applied to atmospheric pollution control. They emphasize the need for “further research and field study, particularly with respect to the collection of dust and fumes, to provide basic information on stack gas cleaning equipment and other control measures especially for small plants.”

Many large and small cities in the United States have recognized the problem of atmospheric pollution and have passed ordinances regulating smoke or smoke and dust, while some of the large cities have a relatively complete coverage of the important atmospheric contaminants. No attempt has been made in this report to make a nation-wide survey of the administrative control of atmospheric pollution. However, for illustrative purposes, information was obtained

on control practices in three large cities; namely, New York, St. Louis, and Los Angeles, which have organized control programs.

Control of atmospheric pollution in New York City* is an activity of the Bureau of Sanitary Engineering of the Department of Health under the general supervision of the Sanitary Engineer Director of the Bureau.

A special force of smoke inspectors has been organized consisting of one supervising inspector and six field inspectors. The regular district inspectors (approximately 70) take care of the routine complaints of smoke, odors, fumes, etc. The special smoke inspectors make investigations involving larger plants, utilities, harbor craft, etc. They also make surveys of air pollution in areas of greatest intensity of smoke discharge. The supervising smoke inspector checks over the work of the regular district inspectors in air pollution.

The district inspectors, in groups of five are given an intensive course by the supervising smoke inspector in methods of investigating and controlling air pollution. The course takes about six weeks.

Eleven committees have been organized to cooperate with the Health Department. These committees represent: (1) real estate and industry, (2) railroads, (3) utilities, (4) harbor craft, (5) solid fuels, (6) fuel oils, (7) public health aspects, (8) laws and legislation, (9) plant operation, (10) city departments, (11) public cooperation. The committees have met in most instances monthly with the Commissioner of Health and the Director of the Bureau of Sanitary Engineering.

Monthly sootfall collections have been made for the past five years from 13 locations, mostly in areas of high smoke

discharge. These monthly samples have been analyzed for solids and ash in both the water-soluble and water-insoluble components of the sample. The results obtained, when compared with those of previous periods, give a rough estimate of the increase or decrease in smoke discharge over wide areas of the city.

In comparison with the sootfall records obtained during a WPA air pollution survey in 1936, recent results show that there was a large increase in sootfall during 1943 and 1944, which has subsequently lessened considerably. The increase during the war period was concurrent with a tremendous overloading of coal-burning power plants.

A great amount of rehabilitation of fuel-burning plants and installation of soot collectors has been accomplished during the past two years. The large electric companies have made significant improvements at their generating plants at a cost of millions of dollars. A number of the industrial plants, hospitals, and mercantile establishments also have improved their fuel-burning equipment and put in soot collectors.

A detailed program for the extensive training of janitors and superintendents has been prepared and will start in the fall of 1947 in some of the Board of Education high school buildings.

At the same time that the janitors and superintendents are acquainted with methods of firing furnaces and preventing smoke and odor complaints, they will be given instruction in rodent and vermin control and in the sanitary maintenance of buildings.

A program for future extension of this work has been drawn up and will include the addition to the department of a mechanical engineer—an expert in smoke control work, two assistant engineers, and a number of field inspectors. This expansion is now awaiting the allotment of funds by the city authorities.

* Information concerning New York City was furnished by Sol Pincus, Senior Sanitary Engineer, New York City Health Department.

St. Louis* has attracted considerable national attention because of the extent of its air pollution problem and the efforts made to control it. These efforts, principally due to the anti-smoke ordinance and its enforcement, appear to have produced a definite and permanent improvement. This is particularly true of sootfall, visible smoke, and volatile sulfur compounds in the air caused by combustion of solid fuels.

The city, being located close to the Southern Illinois high-volatile bituminous coal fields, uses such fuel in great quantity. The anti-smoke ordinance secures the control of the pollution of air from such fuel use by a multiple approach:

1. It prohibits the use of high-volatile bituminous fuel except in mechanically-fired furnaces and power plants.
2. It requires the air- or water-washing of all high-volatile bituminous fuels to reduce sulfur compounds.
3. It sets certain limits for fly ash emission which invariably require collector installations on powdered-fuel power plants.
4. It has the usual and necessary measures of promoting proper firing, registration of new heating installations, maximum density and duration limitations for smoke emission and a qualified inspection force.

Enforcement of the anti-smoke ordinance is the responsibility of the Commissioner of Smoke Regulation who directs a division which is a part of a Department of Public Safety. The Health Division, a part of the Department of Public Welfare, works closely with the smoke control office and has assisted in providing some technical assistance, particularly along the lines of laboratory and air analysis techniques.

Most of the present air pollution problems center in fly ash emission from plants permitted to postpone collector installations due to wartime equipment

shortages and such emission from large plants near to but outside the city limits and, therefore, beyond the city's legal jurisdiction. Some smoke and chemical odor problems occur at times due to such materials being carried over the city from the highly industrial area just to the east of the city, in Illinois.

The remaining air pollution problems are, in general, not city-wide but rather limited to local neighborhoods, and are due to isolated industries producing objectionable dusts, fumes, or gases. Almost invariably, these cannot be demonstrated to be either a health hazard or a public nuisance (involving property damage over a considerable area). At present, the city charter and ordinances give power to the Health Commissioner to declare and abate public nuisances (after hearings). Those air pollution situations which come within this category can be and have been controlled by this legal means. The Health Division has extensive air sampling equipment and experienced personnel in its Industrial Hygiene Section. Through these means, it is able to locate responsibility and recommend and enforce corrective action.

The inadequacy of present laws for air pollution problems not of public nuisance proportions is recognized. Plans are now being made for the formulation of an overall air pollution control ordinance. Provision for an adequate and qualified staff is also planned.

The Los Angeles* air pollution control problem differs from that of most eastern cities. No coal is burned; instead gas is used by all homes and by most apartment buildings and hotels. In summer most industrial power plants are operated by gas, while in winter large power and heating installations employ oil burners.

The greatest accumulation of smoke

* Information concerning St. Louis was furnished by John Buxell, Engineering Director, St. Louis Health Division.

* Information concerning Los Angeles was furnished by Charles L. Senn, Engineer-Director, Sanitation Bureau, City Health Department.

and other air pollution is associated with hot summer weather when visible smoke production is at a minimum. This is due to the occurrence of extreme temperature inversions coupled with an almost complete absence of wind and turbulence.

A city ordinance places certain responsibilities for air pollution control on the Los Angeles Health Department. The Air Pollution Control Division of the City Health Department is one of the divisions of the Sanitation Bureau. The division personnel consists of a director, four inspectors and a clerk-stenographer. One inspector is responsible for collecting samples and for studies of industrial fumes and gas nuisances. A second devotes his entire time to railroad smoke control. A third is concerned principally with the control of smoke from Diesel trucks. The fourth inspector is assigned to the harbor district which includes the two major oil refineries which are located in the city.

Most of the control work is based on the use of the Ringlemann chart and on organoleptic tests. The facilities of an industrial hygiene laboratory are available. Samples are collected with electrostatic precipitators and two scrubbing devices. The main laboratory effort has been directed toward attempting to isolate the particular chemical that acts as a lacrimator, since eye and throat irritations are the principal causes for complaint by citizens.

The present status of the organization of the Department of Health is somewhat questionable because of newly enacted state legislation. An amendment to the State Health and Safety Code sets up a state-wide control system concerning smoke, dust, obnoxious gases, and industrial waste fumes discharged into the air. The act provides for the creation of smoke abatement districts that would be under the direct supervision of county boards of super-

visors, whose authority would supersede that of an incorporated city except where local ordinances are stricter than the state law.

It is obvious that the engineer must play an important part in the control of air pollution. The position of the engineer in this field and the knowledge necessary to function satisfactorily were discussed by Phelps and others²⁰ in a symposium on "The Role of the Engineer in Air Sanitation," of the American Society of Civil Engineers, 1941.

DISCUSSION

The control of atmospheric pollution is an administrative and technical problem that can be solved by engineering means. While there is no epidemiological information that will permit evaluation of the public health significance of many of the recognized air contaminants after they have been discharged into the atmosphere, their importance from the standpoint of the comfort and general welfare of the public and the individual involved cannot be overlooked.

The pollution of the atmosphere by dust, smoke, fumes, gases, vapors and mists as well as by pollen, should engage the attention of health departments at all levels of government, and qualified engineers should be called upon to meet health department responsibilities in this field of environmental sanitation.

The organization of the necessary administrative and technical activities in a health department will be governed to some extent by the facilities that can be made available. Trained professional personnel and technical facilities are required if air pollution is to be abated.

Since other departments of government too are concerned, directly or indirectly, with this problem, a coordinated program of activities is indicated.

There is an obvious need for research on many technical phases of atmospheric

control, especially on the meteorological factors affecting atmospheric pollution, methods for the instrumental measurement of odors, methods for the collection of dusts and fumes from industries, and methods for the control of air-borne pollen.

Course on Financial Problems in the Nursing Field

A short course on Financial Problems in Schools of Nursing, Hospital Nursing Services and Public Health Nursing Agencies, 2 semester hours, will be given July 12 through 23, 1948, in the Division of Nursing Education, Indiana University, Bloomington, Ind.

This course is especially designed for directors of basic nursing curricula, directors of hospital nursing services, and directors of public health nursing

agencies. It should also be of interest to board members of public health nursing agencies, hospital administrators, and college and university administrative officers who are concerned with basic nursing curricula.

Information and application forms may be secured by writing Mrs. Eugenia K. Spalding, Director, Division of Nursing Education, Indiana University, Bloomington, Ind.

The Sanitary Engineer in Hospital Construction and Maintenance*

A. H. WIETERS, F.A.P.H.A.

Director, Division of Public Health Engineering and Industrial Hygiene, State Department of Health, Des Moines, Iowa

THE greatest hospital construction program in the history of this country was launched with the passage (by the 79th Congress) of the Hospital Survey and Construction Act (P.L. 725). This act authorizes an annual appropriation of \$75,000,000 for each of five years for grants-in-aid for the construction of hospital facilities. The program is to be administered largely by the states under the general supervision of the U. S. Public Health Service. One of the provisions in the act requires the states participating in the program to regulate the operation and maintenance of the hospitals built with federal aid.

Only a few states previously regulated construction and operation of hospitals, but now, for the first time, the construction, maintenance, and operation of most hospitals will be under state regulation. In about three-fourths of the states, the health department will be the administering agency.

A comprehensive nation-wide inventory of existing hospitals and survey of needs for hospitals in the United States in 1945 revealed not only a great shortage of adequate hospital facilities, but also a serious maldistribution of existing facilities. Thus, a large segment of the total population finds itself with no hospital facilities readily available. Furthermore, the inventory revealed that many of the existing services failed to

provide acceptable hospital care by any reasonable modern standard because of grossly inadequate physical plants and staffs. Consequently another large segment of our population lacks satisfactory hospital facilities.

Time will not permit, nor is it within the scope of this paper, to discuss these needs. Suffice it to say that the objective of the present program is to assist the several states to survey their needs for hospitals, to develop plans for construction of facilities for furnishing adequate hospital services for all the people, and to construct such hospitals.

Many professional skills must be combined in the development of construction plans for a modern hospital. The hospital is more than a building. It is a workshop and, as such, the building layout and the type and arrangement of equipment must be carefully planned so that the entire facility will function effectively and economically. The hospital and its equipment are the tools used by the physicians, the nurses, and allied technical hospital personnel in caring for the sick.

Obviously, those responsible for operating the hospital must have a voice in the functional planning. Equally important are the engineers and architects who translate the functional plan into a working drawing and a finished facility. The final plan must be the result of close teamwork of those representing the various and highly technical skills involved.

* Presented before the Engineering Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

In the operation and maintenance of a hospital, again teamwork is essential for successful and economical service. All of the engineering problems encountered in ordinary building operation, plus many additional ones, must be solved. These are made the more difficult in that even short lapses in operation of any of the equipment or appurtenances cannot be tolerated and much maintenance must be carried out while the plant is in full operation.

The sanitary engineer should be a member of such a team. While sanitary engineering principles have long been applied in hospital construction and maintenance, the sanitary engineer has not been closely identified with hospitals to any great extent in the past. A few large architectural firms specializing in hospital design have formerly employed sanitary engineers; however, most architects do not have sanitary engineers on their staffs. In only a few of the states have architectural plans been subject to review by sanitary engineers. Likewise, in but few of the states and larger cities has the sanitary engineer been called upon to contribute his services in the operation and maintenance of hospitals.

Most of the principles of hospital sanitation are the same as are applied to other types of buildings; however, the hospital is unique in that many of the occupants are potential, if not known, active carriers of disease. Therefore, faulty design, breakdown, or lapse in proper use and operation of equipment is fraught with greater danger of spread of disease than would be the case in other buildings. Also the occupants are, for the most part, in a weakened condition and thus are more susceptible to ill-effects from faulty environment than are occupants of other buildings.

As previously stated, in both the design and operation of a hospital, the functional as well as the architectural and engineering phases must be coördi-

nated for efficiency and economy. The sanitary engineer is in a unique position by training and experience to serve in a liaison capacity between those doctors, nurses, hospital administrators, and others responsible, on the one hand, for operating the hospital, and the engineers and architects responsible for design, construction, and equipping of the hospital on the other.

What is the extent of the sanitation problems in hospitals? Complete morbidity statistics would be the best criterion for the evaluation of sanitation problems. Unfortunately such data are very incomplete. It is known that there are numerous recurring outbreaks of diarrhea and skin infections among infants in hospitals, of food poisoning, and of cases of cross-infections which are never reported to health authorities. It is also known that many of these cases of disease result from faulty environment. That potential hazards, readily recognized by sanitary engineers, are commonly found in hospitals is indicated by many surveys that have been made. In existing buildings, serious defects in plumbing have been very common. According to a recently published report, food sanitation in the hospitals in one of our largest cities was rated lower than in the public restaurants in the same city, and in the latter was far from satisfactory. Crowding, lack of sufficient good equipment, and unsatisfactory working spaces and equipment are known in many cases to be more responsible for breaks in technique which result in spread of disease than incompetence of employees.

The sanitary engineer is largely concerned with the sanitary features of structures and equipment and their maintenance and operation. However, these are so closely related to functional and other features of design that a distinct line of demarcation cannot be drawn. The layman, and even other professional engineers, too often do not

seem to realize that the sanitary engineer is basically trained in fundamental engineering principles in common with other professional engineers in addition to his training in public health.

Many phases of professional engineering are involved in hospital design, construction, maintenance, and operation, and more than one specialty is frequently required in the design of a piece of equipment. For example, a dishwashing machine may be designed by a mechanical engineer. However, there are important sanitary implications in the design, the installation, and the operation of such a machine which must be considered in the interest of public health.

The services of the sanitary engineer in hospitals should be utilized in two ways: (1) in design, maintenance, and operation of facilities and equipment which comes more or less within the scope of his usual activities, many of which, however, have special significance in the hospital; (2) in coöperating with the medical and allied professions, in further study of potential health hazards in the environment of the patient about which little is known.

In the first category, the following items may be enumerated:

Site—Many future sanitary problems of maintenance and operation can be avoided by proper site selection. Availability of an adequate, safe water supply, proper drainage, and means of safe and economical disposal of sewage and wastes are very important factors in site selection. Insect breeding areas, sources of noise, smoke, and dust in the immediate area must be given careful consideration.

Sewage disposal—Where no sewer system is available, sewage disposal may be a particularly troublesome problem. Because of the potentially infectious nature of the sewage from a hospital, a high degree of treatment and special precautions are necessary. Large volumes of laundry and cleaning wastes may complicate the treatment problem. Operation and maintenance of these facilities likewise require special knowledge, usually not possessed by hospital operating personnel.

Plumbing—Because of a relatively large quan-

tity of infectious material which is introduced into the drain system, plumbing is of special importance. Many special fixtures used in hospitals, and which are not in common use elsewhere, are inherently dangerous unless adequately protected. These factors make precautions against backflow doubly important. Relatively large amounts of water are used in hospitals and peak demands are high. To assure adequate and uninterrupted pressures in all parts of the building under all operating conditions requires very careful design. For the same reason, drains must be carefully planned.

Food Handling—While general sanitary principles in the storage, preparation, and handling of food and the cleansing and disinfection of utensils apply, opportunity for contamination is so great and effects may be so disastrous that unusual precautions are necessary.

Garbage and Waste Disposal—The hospital has the usual problem of the proper disposal of ordinary kitchen garbage and rubbish. Also the handling and sanitary disposal of contaminated and infectious material, which is peculiar to hospitals, presents a problem.

Lighting—In addition to the hygienic and safety aspects of general lighting, special lighting in certain areas, such as surgery, dispensary, formula room, etc., is imperative. Uninterrupted lighting in certain areas is a must item.

Heating and Ventilation—In addition to general heating and ventilation, several areas within a hospital require special consideration.

Laundry—Although commercial laundering practices are quite well standardized, and in modern practice effective germicidal action is incidental to thorough cleansing, the handling of soiled laundry requires special attention.

Sterilization Equipment—Possibility of contamination of the water supply or of the contents of sterilizers is extremely important and the very nature of this equipment makes it difficult to construct sterilizing equipment which is fully protected. Also unless the equipment is meticulously operated and maintained, complete sterilization results will not be uniformly obtained.

General Sanitation—There are many other considerations which will facilitate general cleanliness and good housekeeping, such as floor and wall construction of durable, easily cleaned material, and adequate and conveniently located hand washing and toilet facilities for employees. Insects and rodents often constitute serious problems in hospitals, and control measures, both as to construction and operation, are of great importance.

In a second category, of first importance is the study of the spread of disease from patient to patient, from patient to employee, or the reverse, within the hospital. While this is primarily the function of a trained epidemiologist, the services of a sanitary engineer should be used to a greater extent. In the past, to the writer's best knowledge, sanitary engineers have had little opportunity to assist in such investigations, although it has been common practice for many years to utilize the services of the sanitary engineer in other epidemiological studies where environmental factors were involved.

There are other items on which further information is needed. While perhaps some of these studies should primarily be conducted by professional personnel other than sanitary engineers, it is believed that sanitary engineers could render valuable assistance. No attempt is made to enumerate all such items, but the following will illustrate some of the needs:

Is general ventilation (including temperatures, humidity, and air movement control) indicated in the hospital? Is it permissible to recirculate air in the surgery, the nursery, the labor and delivery rooms, and contagious wards? Is it ever permissible to recirculate air from any one patient area to another?

In view of the limited studies that have been reported, and of the lack of conclusive evidence of substantial benefit, what policy should be adopted on use of ultra-violet ray air sterilization in surgery, nursery, contagious wards, formula room, etc.? On use of aerosols?

Should completely separate dishwashing facilities be required for a contagious section or tuberculosis section? If so, is it permissible to return clean dishes from this section to the general kitchen for serving?

Should linens from the contagious section, tuberculosis section, etc., be laundered separately from the general

laundry? Should linens receive germicidal treatment before being removed from these sections to the hospital or a commercial laundry? If given no such treatment, what special precautions should be taken by personnel who handle such linen in the laundry?

Should feces and urine from known or suspected cases of intestinal infection or other infectious material be germicidally treated before discharge into a public sewer? Or into a private sewer?

What special precautions should be taken in handling and storage of patients' clothing?

Should mattresses in the contagious section be sterilized after discharge of each patient? Does laundering at low temperatures (wool 120° F.), particularly from the contagious section, provide ample protection?

Is it permissible to include food left on plates from the contagious or the tuberculosis section in garbage which is fed to hogs?

Adequate information is not available on peak water usages on which to base intelligent design of water piping and drain systems.

No public laboratory now exists where hospital plumbing fixtures and appurtenances can be tested.

These and many other questions remain to be answered.

One of the requirements for federal aid under the Hospital Survey and Construction Act is that states must regulate the operation and maintenance of hospitals receiving such aid. Under this stimulus, many of the states already have, and most of the others probably will make, provisions for licensing of all hospitals. Sanitation should play a prominent part in any such regulation and thus for the first time in many states the sanitary engineer will have an opportunity to participate in hospital planning, operation, and maintenance.

In most hospitals, various individuals

have responsibility for some phase of sanitation with little correlation or general direction. Probably very few hospitals are large enough to justify employment of a full-time sanitary engineer, yet sanitation problems are of sufficient importance in hospitals of all sizes to warrant more attention than has been accorded them in the past.

It would be desirable, wherever feasible, to have one person on the hospital staff, preferably with sanitation training, who is responsible for all phases of sanitation, with such assistance and guidance of local or state health department sanitation personnel as may be needed.

The state and local health department sanitary engineers should be available to review plans and specifica-

tions, from a sanitation standpoint, for new construction and for revamping existing structures; to make sanitary surveys of existing hospitals and advise as to physical changes and operation procedures which would improve sanitary conditions; to advise and guide personnel who are responsible for operation and maintenance of equipment; to participate in inservice training of employees; and to study means of improving hospital sanitation.

With the advent of a huge hospital construction program, coupled with the control of operation and maintenance of most hospitals by the state, the sanitary engineer is presented an opportunity to extend his services into a field with which he has not been closely identified in the past.

Sanitary Ventilation*

W. F. WELLS, F.A.P.H.A.

*Associate Professor of Research in Airborne Infection, University of Pennsylvania
School of Medicine, Philadelphia, Pa.*

FIFTEEN years ago we demonstrated before a joint meeting of these sections an apparatus for the study of the bacterial behavior of air¹; at the meeting ten years ago we described a method for the measurement of sanitary ventilation²; five years ago we discussed air disinfection in day schools³; this paper considers the sanitary significance of ventilation. Paradoxically, the hygienic interest in ventilation waned with rise of sanitation. Before the patterns of spread of ingested infection and inhaled contagion were clearly differentiated, the sanitary disproof of the miasmatic origin of enteric infection discouraged further belief in air-borne respiratory contagion; transfer of contagious disease then was ascribed to personal contact.

Even in the most congested districts of our largest cities, contact infection was of secondary consideration in the environmental control of typhoid fever. The gradual decline in residual typhoid resulting from elimination of carriers created by water-borne infection came as a minor and unpredicted bonus, compared to the reduced rates immediately following an investment in pure water.⁴ In the control of contagious epidemics on the other hand, such as measles, for instance, or influenza, where a single case can initiate a contagious chain of

growing generations of infection, quarantine has until recently been the only environmental means available. Whereas the relatively static dissemination of infection in space dominates spread of typhoid fever and other water-borne intestinal infections, the propagation of air-borne respiratory contagion in time is intrinsically dynamic.

DYNAMICS OF CONTAGION

The autocatalytic nature of contagion has been expressed mathematically for theoretical epidemics in homogeneous aggregations homogeneously exposed. "Almost all workers in the analytical theory of epidemics assume that the rate at which an infection passes in a population is proportional jointly to the product of the number of persons I who are infectious and the number of persons S who are susceptible to the infection. This is called the law of mass action. Thus, if the rate of new infections be C the law is written as $C = rIS$, where r is a constant,"⁵ r then being the effective contact rate. This elementary equation approximately describes the dynamic pattern of intra-aggregational spread of contagion.

EFFECTIVE CONTACT RATE

In the study of contact infection, measles has played a leading role and is suggested as a natural index for study of the dynamics of droplet nuclei contagion. The value of S in the above formula is directly indicated; persons

* Presented at a Joint Session of the Engineering and Industrial Hygiene Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

The work reported in this communication was supported by grants from the Commonwealth Fund.

are assumed to be susceptible before, and immune after, having measles. Also, the value of I is generally ascertainable; direct exposure to a previous case the second week before symptoms appear can usually be detected; younger children normally contract the disease when exposed in the home.

In a quantitative study of effective contact the suburban primary school offers decided advantages: children ordinarily enter school before having measles but contract this disease before graduation; in school they are homogeneously exposed within standard classrooms; both exposure and effective contact can be established through attendance records.

By such means the effective contact rate r of measles in classrooms of three suburban primary schools during the past four years has been evaluated.⁶ Among approximately 791 susceptible

classmates of pupils who became ill with measles while attending classes (a unit of exposure), 87 contracted the disease after a normal incubation period. An effective contact rate of 11.0 per cent is consistent with unproductive exposures observed in schools⁷ and should theoretically yield in the formula some indication of productive exposures in classrooms meeting with Pennsylvania code requirements of ventilation.

INTRAGROUP CONTAGION

As compared with 80 or 90 per cent secondary attack rate among primary school children in families reported by Chapin,⁸ an effective contact rate of 10 per cent in classes may seem unimpressive, but this represents merely the static infection in a single generation. Most of the infected pupils attend class until symptoms appear, and by re-exposing their class become the infectors

THRESHOLD SANITARY VENTILATION

CHART I—Diagram Relating Sanitary Ventilation to Air-borne Contagion

Area inside each link of chains of generations of infection in irradiated and unirradiated schools during 1941 epidemic corresponds to percentage of susceptible pupils infected in that generation period, i.e., week and half. Center of largest link indicates number of susceptible pupils sharing ventilation at peak of epidemic when generations begin to decline, thus locating threshold sanitary ventilation per susceptible pupil. Chart on which chains are constructed described in Dynamics of Air-Borne Infection, *Am. J. M. Sc.*, 206:11-17 (July), 1943.

of a second generation. This linkage of cases in one generation to infectors of the next forges the chains of successive generations illustrated on Chart 1.

Obviously while cases exceed infectors rS is greater than unity and generations are growing, reach a "steady state" at the peak of the epidemic when $rS_T = 1$, and decline when infectors exceed cases, or rS falls below unity. The "density" of susceptible persons, S_T , at the epidemic peak, or the reciprocal of the effective contact rate, is called the "threshold," because if this "density" is not maintained by accession of persons susceptible to the disease, as when contagion becomes endemic, cases are sporadic and the disease dies out. During an epidemic the "density" theoretically falls as far below as it started above the "threshold," though our school results seem to indicate a proportional rather than an absolute relationship.⁹

To one accustomed to the erratic behavior of measles in classes such an orderly array may seem unrealistic, yet the diagonal on Chart 2, approximating the computed total infections for classes of differing susceptibility, portrays diagrammatically the pregnant fact that the percentage of susceptible pupils who contract the disease when introduced into classes increases with the number of susceptible children in the classrooms. The reality of this fact is indicated by the percentage of susceptible pupils in different grades of a large centralized school near Syracuse who contracted measles during a recent epidemic.¹⁰ With enrolled classes of 33 pupils (an approximate average) the numbers plotted on the chart correspond with percentages of susceptible children in the grades. Since the cases contracted outside the classroom are included in these data, the plotted number of cases per 100 susceptible children exceeds somewhat the number resulting only from dynamic spread of measles

within the classroom. Nevertheless it becomes evident that "crowding" is a major factor in the contagiousness of measles.

SANITARY VENTILATION

Now in terms of droplet nuclei infection, S is proportional to the amount of infected air breathed by susceptible persons; I to the amount of infection contributed to the air by the previous generation of cases; and r to the dilution of infection afforded by ventilation, or to the reciprocal of VS , where V represents ventilation per susceptible occupant (Chart 1). The substitution of these factors has proved the basic equation of the law of mass action to apply in quantitative experimental air-

CHART 2—Increasing Percentage of Susceptible Pupils Who Develop Measles as Number of Susceptible Pupils per Classroom Increases

Diagonal approximates percentage computed with 10 per cent effective contact rate per generation. Marked circles indicate percentage of susceptible pupils in primary grades of Mexico School who developed measles in 1946 epidemic (10). Percentage of susceptible pupils corresponds to 33 pupils per class (approximate average).

borne tuberculosis in rabbits.¹¹ Since rS_T becomes unity at "threshold density of susceptibles," ventilation per susceptible occupant at this "density," V_T , becomes the natural sanitary unit of ventilation and the law of mass action, as applied to air-borne contagion, then becomes $CV = IV_T$. Only below threshold ventilation, or when V is less than V_T , can droplet nuclei contagion become epidemic; cases are sporadic when V exceeds V_T , and the infection dies out.

Ventilation is usually expressed as cubic feet of fresh air replacement, or cubic feet per occupant—per susceptible occupant in sanitary ventilation. Sometimes it is more convenient to express ventilation in air changes of confined atmospheres, and if a *lethe* of disinfection is defined as the bactericidal equivalent of bacterial removal by dilution with one air change (one volume pure air replacement with continuous mixing), sanitary ventilation by air disinfection can be expressed in cubic foot-lethes.¹² By principles underlying these transformations elaborated elsewhere,² sanitary ventilation can be measured bacteriologically by the equilibrium concentration of standard test organisms, atomized at a constant rate into an enclosed atmosphere at representative locations, determined at another representative location with and without air disinfection. Multiplying the die-away rate without disinfection by the ratio of equilibrium concentrations gives *lethes*, or equivalent air changes.

Radiant disinfection of air in primary schools has played a dominant role in the experimental study of sanitary ventilation. The number of air-suspended bacteria killed by irradiation of a dry confined atmosphere can theoretically be deduced from a generalized hypothesis combining three accepted laws: the inverse square law of radiant intensity; the Roscoe-Bunsen law of

reciprocity of time and identity of exposure; and the quantum (logarithmic) law of disinfection.¹³ By this hypothesis the number killed becomes proportional to the number of photons, or to ergs of radiant energy intercepted by living bacteria. If a ray be regarded as a constant stream of photons, then the number of photons in a confined atmosphere is proportional to the total lengths of the rays between the points of entrance and disappearance from the enclosed space. Dividing the volume of the room into this total length, or the sum of the products of the rays into their length, gives average intensity. Thus, radiation in watts multiplied by average ray length in feet gives total irradiation in foot-watts which, divided by room volume in cubic feet gives average intensity in watts per square foot.

This reciprocal relationship between radiant flux and distance traversed through an enclosed space is obvious with uniform light intensity. Thus, one watt of uniform parallel light, such as sunlight, traversing 10 feet of a transparent column 10 feet long and of 1 square foot cross-section, will irradiate 10 cubic feet to 10 foot-watts, or 1 foot-watt per cubic foot, giving an intensity of 1 watt per square foot. In like manner, 10 watts falling perpendicularly upon 10 square feet of a side, passing through 1 foot of this column, will also irradiate 10 cubic feet of air to 10 foot-watts, giving average intensity of 1 watt per square foot. In any position or in any form, 10 cubic feet would be irradiated by 10 foot-watts, the product of the flux into mean ray length. Regardless of the form of the space or the direction of the rays, irradiation is given by radiant flux multiplied by mean ray length.¹⁴

It follows from the generalized law of radiant disinfection that the greatest number of organisms suspended in a given volume of air are killed when uni-

formly exposed to a given amount of irradiation, the lethal efficiency of uniform irradiation therefore being a maximum. We were unable to irradiate large spaces uniformly but were able to devise a chamber providing uniform exposure to a point source at the center, toward which air flowed with a velocity inversely proportional to the square of the distance from the source. The product of time and intensity of exposure of air-borne organisms to the source was therefore constant at any point, and the determined foot-lethes divided by computed foot-watt minutes of exposure, or the product of average intensity by time of exposure, gave the lethal equivalent of irradiation. Against standard bacterial suspension in dry air 0.002 foot-watt minutes of irradiation in the 2537Å wave band was equivalent to a cubic foot-lethe, less than a tenth of the irradiation required in humid air, on moist agar surfaces, or in aqueous suspension.¹⁵ If radiation in this wave band be adopted as standard lethal radiation, then a foot-watt minute of standard uniform lethal irradiation is equivalent to 500 cubic foot-lethes of standard air disinfection, or cubic feet of sanitary ventilation.

But it is not feasible to irradiate the occupied zone of a room to the desired average intensity; and, so, irradiation efficiency in practice depends upon design. Generally the amount of irradiation realized from a radiant source in an enclosed space depends directly upon mean ray length; the uniformity of irradiation of the space normally increases with mean ray length, the uniformity of exposure depending upon air circulation usually increases as rays are lengthened; and the disinfection of organisms en route from occupant to occupant approaches average disinfection as rays are lengthened. The hygienic rating of disinfection thus increases *inter alia* with mean ray length.¹³

The role of air circulation in equal-

izing exposure of air-borne organisms to differing intensity in ventilated spaces is little appreciated by those who have not measured radiant disinfection by bacteriologic procedures. With good design, air circulation between the occupied and upper irradiated zone, expressed in terms of the amount of recirculation of the air through a chamber uniformly irradiated with the given number of foot-watts exceeded three air changes per minute. Thus, by radiant disinfection with 6 foot-watts per pupil, more than twenty times the sanitary equivalent of standard school ventilation—exceeding threshold sanitary ventilation (Chart 1)—has been attained in experimental schools.¹⁶

DYNAMIC EXPERIMENT

Measles epidemics would not propagate in these schools according to the dynamic hypothesis discussed above. Records^{17,16, 4, 6 *} of nine years' experience in the irradiated Primary Department of the Germantown Friends School and six in the two Swarthmore Primary Schools, as compared with four years' experience in the unirradiated Primary Department of the William Penn Charter School and the two Nether Providence Primary Schools, indicate that:

1. The effective contact rate of measles in classrooms was reduced; per hundred susceptible classmates of a pupil becoming ill with measles while attending class (unit of exposure) 11.0 contracted the disease in unirradiated schools, during the second following week, as against 3.1 in irradiated schools.

2. The dynamic spread of the measles in the school was checked; per hundred susceptible pupils of unirradiated schools more than twice, and in classrooms more than five times, as many were infected.

3. The community threshold for primary school children was raised; per hundred pupils in unirradiated primary schools, half again as many had had measles.

Q Fever in Los Angeles County

Description of Some of Its Epidemiological Features

CHARLES C. SHEPARD, M.D., AND
ROBERT J. HUEBNER, M.D.

Division of Infectious Diseases, National Institute of Health, Bethesda, Md.

Q FEVER has been found to occur in Los Angeles County, California, in an apparently endemic fashion, and this paper describes certain characteristics of the disease in that area.

Two naturally occurring outbreaks of Q fever are known to have taken place in the United States. The first appeared in Amarillo, Tex., in March, 1946,¹ and the second in Chicago, Ill., in August, 1946.² These two epidemics were alike in many respects; both were sharp outbreaks arising from occupational exposure of susceptible persons to stock being slaughtered or moving to slaughter. The attack rates were high in both instances, being over 50 per cent in the most heavily exposed groups, and the dates of onset of the cases were distributed over a 2 to 3 week period, the variation being chiefly accounted for by the spread in incubation period of the human disease.

It seemed clear from studies of the two outbreaks that infected cattle in Amarillo and infected calves or sheep in Chicago had been the source of human infection, and that transmission to slaughter-house workers had come from infected tissues and body fluids either by direct contact or by means of droplets of splattered fluids. Ticks had been very rarely seen on animals in either of these locations, and, in Chicago, cases did not tend to develop in persons associated with operations on hides, but instead were concentrated in personnel handling viscera.

Although the means by which the human beings had become infected was somewhat clarified by these studies, the manner of infection of the animals was not obvious, and it was not possible to gain a clear picture of the natural reservoirs of the disease in this country. For one reason the infectious source had long since been removed when the outbreaks occurred, and the epidemiological investigations were necessarily retrospective. The endemic area now found in Los Angeles County appears to provide suitable material for investigation of the natural reservoir problem.

The apparent lack of an insect vector in the two American outbreaks and their explosive and isolated nature seems to be different from the picture in Australia.³

THE OUTBREAK IN LOS ANGELES COUNTY *General Description of Area—*

The cases which have been found have developed in the milk shed area of Los Angeles County. This zone is in flat land 10–30 miles southeast of the center of the city of Los Angeles. The climate is warm and dry and moderated considerably by the Pacific Ocean.*

This dairy area is one of the most concentrated in the world. There is

* Weather bureau records show that in Los Angeles since 1877 the average yearly rainfall has totaled 15.55 inches with 14.22 inches of this falling in the months from November through March. The average temperature for the same period has been 63.0° F. with monthly means varying from 55.6° in January to 71.4° in August. In 1946 the highest temperature was 95° and the lowest 38°.

TABLE 1
Human Cases of Q Fever

| No. | Age | Sex | Pneumonitis | Days of Fever | Date of Onset | Complement-fixation titer | Date Sample taken | Remarks |
|-----|-----|-----|---|---------------|---------------|---------------------------|-------------------|---|
| 1 | 62 | F | By x-ray | ? | 11-20 | 128 | 5-25 | No definite exposure to dairies recalled. |
| 2 | 51 | M | By x-ray | 11 | 11-25 | 128 | 6-7 | Had visited small farms. |
| 3 | 31 | M | By x-ray | 21 | 12-28 | 128 | 5-27 | Visited dairy occasionally. |
| 4 | 35 | M | By x-ray | 10 | 2-6 | 128 | 4-28 | Visited dairies frequently. |
| 5 | 29 | M | By x-ray | 9 | 2-11 | 256 | 5-26 | Visited dairy about 3 weeks before onset. |
| 6 | 15 | M | Physical findings and bloody sputum | 21 | 2-23 | 512 | 4-28 | Frequently played around dairy. |
| 7 | 45 | M | Physical findings | 6 | 4-6 | 64 | 5-21 | Had visited dairies. |
| 8 | 32 | F | Physical findings and bloody sputum | 10 | 4-13 | 512 | 4-28 | Home 100 yards from several dairies. |
| 9 | 27 | F | By x-ray | 12 | 4-20 | 512 | 6-4 | Home 100 yards from dairy. |
| 10 | 30 | M | By x-ray | 12 | 4-24 | 128 | 5-22 | Two dairies across street. |
| 11 | 28 | M | By x-ray | 11 | 4-26 | 0 | 4-30 | Visited dairy 1 27 days before onset. |
| 12 | 50 | M | By x-ray | 12 | 5-1 | 64 | 5-16 | Cows kept in field beside house. |
| 13 | 35 | F | Physical findings | 6 | 5-10 | 128 | 5-17 | Home 200 yards from dairy. |
| 14 | 36 | M | Physical findings | 7 | 5-14 | 0 | 5-21 | |
| 15 | 26 | F | No x-ray. No physical findings of pneumonitis | 10 | 5-15 | 512 | 5-16 | No definite exposure to dairies recalled. |
| | | | | | | 4 | 5-23 | Wife of Case No. 10. |
| | | | | | | 512 | 6-4 | |
| 16 | 30 | M | By x-ray | 8 | 5-20 | 0 | 5-26 | Home 100 yards from several dairies. |
| 17 | 39 | M | By x-ray | 10 | 5-22 | 512 | 6-5 | |
| | | | | | | 0 | 5-28 | Home surrounded by dairy pens. |
| | | | | | | 128 | 6-2 | |
| | | | | | | 128 | 6-9 | |

as has been described by others. The onset was acute with fever, headache, chills or chilly sensations, and body aches and pains. Cough was frequently complained of but was not a prominent symptom. The sputum which was sometimes produced was at times blood-tinged. Chest pain was common and was usually of a lateral distribution, although a feeling of substernal congestion was frequent. Physical examination of the chest often revealed little of note except perhaps suggestive findings. Respirations were elevated when pneumonic involvement was extensive. Roentgenography revealed a pneumonic process which was usually diagnosed as "atypical" pneumonia when patchy, and "early lobar" pneumonia when diffuse. The leucocyte count tended to be normal or slightly elevated. The illness ran a course of 1 to 3 weeks' fever with

prolonged convalescence especially in older patients. No deaths were found which could be attributed to Q fever.

Many of the patients had recovered when first visited and the criteria of diagnosis had then to be a typical clinical history and the presence of specific complement-fixing antibodies. When patients were seen in the acute stage, blood was obtained, so that a rise in antibody titer could be shown with a later specimen. In addition the clot from the acute stage blood was inoculated into guinea pigs in an attempt to isolate *R. burneti*. It is felt that the diagnosis was firmly established by the demonstration of a marked rise in antibody during the illness or by the isolation of the etiologic agents.

Isolation of *R. Burneti* into guinea pigs was successful in cases No. 8, 11, 14, and 16. The strains were also es-

their antibodies in the course of their work, the results indicate the rate of exposure, since some of them had developed antibodies in less than one year's experience. The dairy workers with negative sera could have become so after having been positive at an earlier date, so that it is possible that more of them had been positive at one time or another. We have observed that after laboratory-acquired Q fever in human beings the sera revert to negative in the course of several years.

Table 3 shows the complement-fixation results with sera gathered from persons who had been ill with diseases which were presumably not Q fever. Although they gave histories of upper respiratory infections, blood samples were obtained and their sera were examined for Q fever antibodies. Though the number is small, the results show that sera of people living near the dairies, but not in actual contact with the cows may also show Q fever antibodies. Some of those with positive serology said they had never visited the dairy near which they lived.

In Table 4 are shown the results on sera obtained from the Los Angeles County and the District of Columbia laboratories. They were in both cases routine sera found negative in serologic tests for syphilis. Those from Los Angeles County were selected because the donor's residence had been given in the general milk shed area. Actually most people living in this area do not

live close to the dairies, since the human population is concentrated in towns, and the dairies are for the most part distributed about the countryside. Of the 166 specimens examined, 5 were found positive in low dilution. The 96 sera from the District of Columbia were all negative. The incidence of positive sera from the Los Angeles County milk shed is low, -3.0 per cent, but none were expected from previous experience.

The results of Tables 2, 3, and 4, when considered together, show that positive complement-fixations for Q fever can be expected in this area on sera of persons not undergoing obvious attacks of Q fever. Although some of the persons with positive sera were not questioned about previous illness, many were questioned at some length, and no definite history of Q fever could be obtained.

Serologic Studies on Sera of Cows—

We have previously examined, by the complement-fixation test for Q fever, bovine sera from two general areas. Nearly sixty sera of beef cattle from Texas and states adjacent to the Texas Panhandle were found negative last year, and more than sixty sera from Maryland milk cows were found negative at the same time.

It was possible to sample the cows at 9 different dairies in the Los Angeles milk shed area and to study the blood sera for complement-fixing antibodies for Q fever. The dairies were distributed across the milk shed area. Table 5

TABLE 5
Complement-fixation Results on Sera of Cows from Several Dairies in Area

| Dairy No. | Number of sera | Number Negative | Number Positive | 4 | 8 | 16 | 32 | 64 | 128 | 256 | 512 |
|-----------|----------------|-----------------|-----------------|---|---|----|----|----|-----|-----|-----|
| A | 9 | 9 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| B | 13 | 11 | 2 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 0 |
| C | 12 | 11 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| D | 20 | 18 | 2 | 0 | 2 | 0 | 0 | 0 | 0 | 0 | 0 |
| E | 16 | 10 | 6 | 0 | 0 | 2 | 2 | 1 | 1 | 0 | 0 |
| F | 15 | 12 | 3 | 0 | 0 | 0 | 0 | 0 | 1 | 1 | 1 |
| G | 15 | 14 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 |
| H | 15 | 14 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| I | 15 | 10 | 5 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 0 |
| Total | 130 | 109 | 21 | 0 | 4 | 3 | 4 | 4 | 3 | 2 | 1 |

gives the results. In all, 130 sera were examined and 21 were found positive, 10 of them in dilutions of 1:64 or higher. The incidence of positives, 16.2 per cent, found in this survey varied from one dairy to another and was highest in dairy E and lowest in dairy A. The significance of the difference in the rates is probably not great, and there was some evidence that Q fever infection was present in all of them. For example, in dairy A several of the dairy workers were found to have positive sera. Other dairy workers of Table 2 were employed at dairies E, F, G, H, and I, and the patient in Case 11 visited dairy I 27 days before he became ill.

DISCUSSION

Although only 17 cases are listed in Table 1, it is likely that many more cases have occurred in the Los Angeles area. The complete reporting of Q fever must depend upon increased awareness of its presence by the physicians of the area, and the adequate use of laboratory diagnostic facilities. Most of the persons listed in Table 1 were patients of a few physicians who were especially interested in discovering cases.

The patients listed in Table 1 as having undergone clinical illness with Q fever did not have intimate contact with cows, and this point merits comment since it tends to cause confusion. Many people deny contact with cows except when they have touched them. As has been stated the "contact" of the persons in Table 1 arose from their living near dairies or having visited them within the incubation period of the disease.

None of the clinical cases found developed in dairy workers, yet evidence for the frequent infection of dairy workers was obtained by serological studies. Half of the 20 dairy workers sampled showed complement-fixing antibodies for Q fever rickettsiae, and it seems likely that others of them had been in-

fectured at one time or another, since positive to negative conversion may take place within a few years. Many of those having antibodies for Q fever did not give histories of illness particularly suggestive of Q fever. It thus appears that the dairy workers had undergone mild or inapparent attacks of Q fever. Mild attacks are known to occur.^{2, 6, 7, 8}

An apparent inconsistency arises from these considerations, that is, the persons with what was apparently the greatest exposure seemed to escape clinical illness. This situation could have arisen from sampling methods, since if mild Q fever were common and severe Q fever rare in this area, and if exposure to the disease were not too greatly concentrated in the dairy workers, the severe cases could have been found in non-dairy workers simply because of their numerical superiority. An alternative explanation also appears possible, namely, that the exposure of the dairy workers is such that it tends to result in the mild disease rather than the severe form.

The complement-fixation results in Tables 2, 3, and 4 indicate that there has been considerable past exposure to Q fever in certain groups of persons in this area. This has apparently resulted in immunity in many cases. In addition it gives rise to difficulties in making a definite diagnosis of Q fever in a particular illness, since the demonstration of complement-fixing antibodies for Q fever rickettsiae in a single specimen taken in the course of a febrile illness is not sufficient to establish the etiology of the fever as being *R. burneti*. In this study, in order to investigate illness which had taken place in the near past we made the diagnosis of Q fever on a single positive serum when the patient had undergone an attack of "atypical" pneumonia. However, whenever the patient could be seen in the acute stage, a sample of blood was taken then, thus making it possible to establish the diagnosis of Q fever with considerable cer-

tainty by demonstrating a rise in antibody in the course of the disease, or by isolating *R. burneti* from the patient's blood, or by both means.

Q fever in the cows of this area appears to be common as judged by the results of the complement-fixation test. It does not appear possible to state definitely that the cows are the source of human Q fever infection since the possibility remains that the same source infected both cows and human beings.

The origin of most of the cattle in other regions suggests the possibility that the infection giving rise to the positive complement-fixations might have been acquired outside the Los Angeles area. However, 3 of the cows positive by complement-fixation were born and raised in the area; their titers were all low (1:8), but such titers seem to be significant, since the cow sera studied heretofore have been completely negative.

The negative results with bovine sera from the Texas Panhandle and adjacent areas and from Maryland were obtained in the course of investigations of an agglutination test using *R. burneti* suspensions as test antigen. Derrick, Smith, and Brown have reported 13 of 879 Australian dairy cows showing agglutinins for Q fever.⁹ However, the agglutination test as we performed it appeared unreliable and of 500-600 bovine sera studied about 60 per cent gave positive agglutination tests. We concluded that the agglutination results we saw were most likely nonspecific and not related to past infection with *R. burneti*.

It would be of interest to know when Q fever infection appeared in Los Angeles County, but it seems that we have little evidence on this point. The first case of Q fever in Table 1 was in a patient whose illness started November, 1946. It is quite possible that cases have been occurring for some time, and it is doubtful if the presence of infection would have become known now had it not been for the recent interest in Q

fever because of outbreaks elsewhere in the country.

It should be noted that few if any ticks are present on the cows in the Los Angeles milk shed, and that the fly population is kept low by DDT spraying of barns and the frequent removal of manure.

SUMMARY

1. Q fever has been found occurring in an apparently endemic manner in the milk shed area of Los Angeles County. Most of the cases lived near or visited dairies.

2. Serological studies revealed that many people who did not give histories of clinical attacks of Q fever showed complement-fixing antibodies for Q fever. Half of the dairy workers and people living near dairies showed specific antibodies.

3. Of 130 sera of cows in the area 21 showed antibodies for Q fever, some in high titer.

ACKNOWLEDGMENT—Acknowledgment must be made of our indebtedness to many people in the course of this work. Frank W. Young, M.D., of Artesia, Calif., suspected Q fever on a clinical basis and sent us a number of sera, many of which were positive by complement-fixation, and it was in this way that the

presence of Q fever in the area was discovered.

Much help was freely given by the personnel of the Los Angeles County Health Department. The coöperation of the local physicians is greatly appreciated, as is the assistance of the dairy owners.

ADDENDUM

Since this paper was submitted for publication, Huebner, Jellison, Beck, Parker, and Shepard have published the results of further

investigations at Los Angeles. *Pub Health Rep.*, 63:201 (Feb. 13), 1948.

They report the finding of *R. burneti*, the causative agent of Q Fever, in the raw milk of 4 dairies in Southern California. Pasteurization results under field conditions, while incomplete, apparently rendered naturally infected milk non-infectious for guinea pigs. Available epidemiological evidence does not indicate that the drinking of milk was the cause of a majority of the cases thus far studied.

Silver Nitrate Still the Preferred Drug in Ophthalmia Neonatorum

In the April issue of the *Woman's Home Companion*, Miriam Zeller Gross, in an article entitled, "Can Present Laws Blind Your Baby?" proposed that the use of silver nitrate be discarded as a method of preventing the infection of eyes of the new-born. She proposes that penicillin be substituted because of its proved value and proved harmlessness.

Among the protests of the scientific accuracy of the article is a report released by the New York Academy of Medicine, on request for an opinion by the Commissioner of Health of New York City. He had some months ago asked the opinion of the Academy about the wisdom of amending the New York City Sanitary Code requirements for silver nitrate.

A digest of Academy opinion follows:

In preventing infection of the baby at birth, both penicillin and silver

nitrate are safe to use when the solutions are prepared carefully and applied properly, a committee of specialists reported. There is no evidence that 1 per cent or even 2 per cent solutions of silver nitrate, which are those used in the prophylaxis of ophthalmia neonatorum, have ever damaged vision.

Bacteria that cause gonorrhea and pneumonia are most likely to cause blindness in the baby, and the concentration of penicillin most effective to halt the growth of these bacteria is not yet known.

In view of the present available evidence of the relative effectiveness of silver nitrate, silver acetate, and penicillin in the control of ophthalmia neonatorum, it would seem that existing laws requiring the use of silver nitrate should not at the present time be revised by the substitution of penicillin for silver nitrate.

Relative Efficiency of the Open and the Confidential Method of Reporting Causes of Death*

PAUL H. JACOBSON

Vital Statistics Analyst, Statistical Bureau, Metropolitan Life Insurance Company, New York, N. Y.

SINCE January 1, 1947, the confidential method of reporting deaths from natural causes has been in use in all five boroughs of New York City. The system had been tried on an experimental basis in the borough of Manhattan during the preceding eight years. The legal and ethical bases for the use of the confidential certificate have been previously reported.¹

Primarily on these bases but also because of its approval by the Committee on Public Health Relations of the New York Academy of Medicine and the five county medical societies of the city, the method was extended to all boroughs. During the first few years of its use in Manhattan, there appeared to be some indications of its statistical superiority,

but no scientific study had been made by means of which its relative efficiency could be impartially evaluated. Accordingly, in November, 1942, Dr. Ernest L. Stebbins, then Commissioner of Health, secured a grant from the New York Foundation for the purpose of making such a study.

HISTORY OF DEATH CERTIFICATION

The registration of causes of death originated with a view to controlling the spread of pestilences, and from the start the statistics of death, by cause, have served as a basis for public health activities. Because of this fact, the registration of vital events in the United States has generally been made a function of state and local health departments.

The ethical aspects of medical certification have been the subject of controversy to a much greater extent in Europe than in the United States. In some countries of Europe, this controversy resulted in the refusal of the attending physician to participate in the reporting of a death or the cause thereof. Switzerland has been a notable exception. More than a half century ago, the Swiss developed a confidential method of reporting causes of death which gave the public authorities information essential to the protection of the public health and at the same time guaranteed the preservation of professional secrets.

In the United States, little if any con-

* This paper presents the findings of the study made by the New York City Department of Health in 1943-1944. The study was carried on under the direction of the late Thomas J. Duffield and the author, with the assistance of Marjorie T. Bellows, Louis Weiner, and their staffs in the Bureau of Records and Statistics. A Statistical Advisory Committee guided the department in the conduct of the study and in the appraisal of the results. The committee consisted of the following members:

Ernest L. Stebbins, M.D., Commissioner of Health, Chairman

Alfred Angrist, M.D., Pathologist, Jewish Memorial and Queens General Hospitals

E. H. L. Corwin, Ph.D., Executive Secretary, Committee on Public Health Relations, New York Academy of Medicine

Godias J. Drolet, Statistician and Assistant Director, New York Tuberculosis and Health Association
Haven Emerson, M.D., Emeritus Professor of Public Health Practice, Columbia University, and Member, Board of Health

John W. Fertig, Ph.D., Professor of Biostatistics, Columbia University

Hugo Muench, M.D., Fellowship Adviser of The Rockefeller Foundation

sideration was given to the question of the confidential nature of medical diagnoses until recent years. A start toward evaluating the problem in this country was made in 1933-1934 when Nicoll and Bellows² showed that syphilis and alcoholism were understated in the Westchester County, New York, mortality statistics. A voluntary system of confidential reporting, which they instituted, was discontinued after several months when found unsatisfactory.³

METHODS OF REPORTING CAUSES OF DEATH

There are two fundamental methods by which causes of death may be reported: (a) the open method, and (b) the confidential method.

(a) *The Open Method*—In the United States, it is the general practice to report deaths on a certificate which requires the following: (i) the name of the deceased, (ii) personal particulars identifying the deceased, (iii) the medical certificate of death, and (iv) information regarding the date and place of burial or cremation. In the medical certificate of death, the physician is expected to state the period of his attendance upon the deceased, the medical diagnoses of the principal and contributory causes of death, the duration of those conditions, autopsy findings, and operations performed.

(b) *The Confidential Method*—In an effort to improve the method of reporting, and at the same time to preserve the essential features of the American procedures, the late Thomas J. Duffield, then Registrar of Records in New York City, in 1936 proposed a confidential system of death certification. After considerable discussion, the Board of Health approved the introduction of the Physician's Confidential Medical Report as an experiment in the borough of Manhattan, commencing January 1, 1939.* Previously, in the entire city, the open form was used, and this form or a similar

one was used in the other four boroughs through December 31, 1946.

Objections to the open form, which are overcome by the confidential certificate, arise from the fact that it has become the practice of custodians of vital records in the United States, as elsewhere, to issue copies of official records of death to relatives for use in the settlement of the affairs of the deceased.

In New York City, for more than a quarter of a century, the certified copies of death certificates issued by the Department of Health have been negative photostatic reproductions of the face of the certificate. Under such circumstances, it is possible that physicians, in keeping with their feelings regarding the ethics of their profession and the law governing professional secrecy, have not always recorded the complete diagnosis of the cause of death to the best of their knowledge and belief. The primary reason for withholding information appears to be the fact that the family physician may not wish to record a diagnosis which offends survivors because it reflects unfavorably upon the memory of the deceased.^{2,5} The fact that a death certificate is of access on legal order and that a copy may be required for the settlement of the estate of the deceased are not thought to be nearly so important in promoting incomplete reporting.† Regardless of the reasons, in stating anything less than the full truth, physicians withhold information that may be im-

* The confidential method, at that time, was also used by Switzerland, and by the cities of Nürnberg, the Hague, and Amsterdam, and to a certain extent in England and Wales⁴; it has since been put into use by the Province of Quebec, Canada.^{6,8}

† The experience of one large insurance company has consistently shown that physicians have no intent to withhold information which can be used for scientific or statistical purposes. A comprehensive published report for their 1911-1914 experience revealed that through supplementary inquiries to physicians the number of deaths attributed to such significant titles as alcoholism, syphilis, and gonococcus infection were increased by 21, 78, and 130 per cent, respectively.⁷ Similar results are evident from unpublished data for recent years.

portant in the planning and administration of public health and related programs.

With the confidential form of reporting, a copy of a death record includes only the following: (i) the name of the deceased; (ii) personal particulars identifying the deceased; (iii) certification that the death occurred on a given date and was due to natural causes, and (iv) information regarding the date and place of burial or cremation. No part of the Physician's Confidential Medical Report, including the causes of death, duration of diseases, and related information appears on the copy of the death record issued to relatives of the deceased. Thus the contents of the confidential medical report are not divulged.

PLAN OF THE SURVEY

In 1943 the Department of Health initiated a study, jointly sponsored by the Department of Hospitals, to evaluate the comparative statistical efficiency of the two methods of reporting causes of death in New York City. A pilot study of 955 deaths which occurred in municipal hospitals in 1941 was completed in the early months of 1943. On the basis of these preliminary statistics, the final plan for the study was formulated, and collection of data started on July 1, 1943.

Objective—The objective of the study was to ascertain whether the confidential method of reporting causes of death resulted in statements of cause of death more nearly in agreement with the physician's knowledge and belief at the time the certificate was filled in than did the open method. It should be noted that the study was not concerned with the accuracy of a physician's knowledge. No method of reporting is able to eliminate diagnostic errors which result from limited clinical examination or medical knowledge; for example, cases in which no operation, biopsy, or other special laboratory tests are performed.*

Criterion—Not all discrepancies between what the physician knows and what he actually records on the death certificate are due to wilful alteration of the known facts. Carelessness, lack of uniformity of definition of terms, and personal interpretation of their meaning are important factors contributing to such differences.¹⁰⁻¹³ To some extent, these differences may be minimized by education and by proper formulation of the questions on death certificates.^{14, 15} Some of these errors were eliminated from the study, by classifying the various individual titles of the 1938 revision of the *International List* into 17 diagnostic groups. Thus only changes from one group to another were considered significant.

In consideration of the above factors, the basic criterion of the study was established as the *correlation between the primary cause of death selected from the statement of cause of death reported to the Department of Health and the primary cause selected from the diagnoses abstracted from the medical case history* (selected and coded according to the *Manual of the International List of Causes of Death*, Fifth Revision, and *Joint Causes of Death*, Fourth Edition, 1939).

The secondary criterion consists of *comparison of the relative frequency with which the following seven conditions (existing or preëxisting) were mentioned anywhere in the case history and on the death certificate: (a) alcoholism, (b) cancer, (c) diabetes mellitus, (d) mental disease, (e) puerperal sepsis, (f) syphilis, and (g) tuberculosis.*

The latter criterion was adopted since it appeared desirable to ascertain the relative completeness with which statements are made on the two certi-

* Because of the deficiencies in clinical diagnoses as revealed by comparisons with autopsy findings,^{8, 9} since June 1, 1947, all autopsy findings for deaths which occur in New York City are reported to the Department of Health on a supplementary confidential medical report.

cates. For example, mental disease is rarely the primary cause of death, but is it more accurately reported as a contributory or associated cause on the confidential death certificate than on the open? Moreover, a sub-sample of 89 cases, independently abstracted by four medical workers, indicated that any method of analysis must assume an indeterminate difference in the primary cause of death due solely to the process of abstraction (individual differences of opinion, etc.). Personal variations are practically eliminated from the data obtained for the conditions specified above (check list). However, if any findings in favor of the confidential certificate are disclosed by these data and not from those on the primary cause of death, they cannot be conclusively attributed to the method of certification. This arises from the fact that the Physician's Confidential Medical Report provides more space for recording the statement of cause of death than does the open certificate.

Selection of Sample—Approximately 28 per cent of the deaths in New York City occur among persons who receive medical attention prior to death and who die at home. These cases afford the best example of the physician-family relationship and might be expected to provide fruitful information for evaluating the efficiency of the confidential certificate. However, no objective method is available for analyzing these cause-of-death statements. The difficulty arises primarily from the fact that case histories in the private practitioner's office are highly incomplete, lack uniformity, or are nonexistent.* As a result, the proprietary hospitals were selected for study, since the role of the physician in these hospitals most closely approximates that of the private practitioner. In contrast, physicians in municipal hospitals do not have such close personal relationship with their patients. It was expected, therefore, that

differences due to wilful alteration of the known facts would not be as great for municipal as for proprietary hospitals. Thus the municipal hospitals were included in the study to serve as a means of interpreting the findings for the proprietary hospitals.†

All proprietary hospitals licensed by the General Inspector's Office of the Department of Hospitals on July 1, 1943, which had been in operation during 1937-1939 and 1941, the period covered by the study, were included in the sample. Nine hospitals — Bellevue, Harlem, City, New York Cancer, and Goldwater Memorial in the borough of Manhattan, and Coney Island, Kings County, Queens General, and Lincoln in other boroughs—were selected for study of municipal hospitals; restricted, however, to deaths reported during January and February of the study years. Because of the small number of deaths involved, the borough of Richmond was not included in the study.

Each borough office of the Department of Health maintains a cross-index file by place of death for all deaths which are reported within the borough. The deaths which occurred in the hospitals selected for study were easily identified from these files. Cases certified by the medical examiner's office were then eliminated by inspection of the death certificates.

Procedure—The Department of Hospitals, which by law is authorized to license and to control the practices of proprietary hospitals, was most helpful in securing access to the hospital records. Dr. Edward M. Bernecker, Commissioner of Hospitals, wrote to the

* The completeness with which syphilis and pulmonary tuberculosis are mentioned on these death certificates could be evaluated by checking the certificates for residents of the city against the department's rosters of known cases. Of much greater value for this and similar purposes, however, it would be desirable to add to the death certificate an item requesting the date and place of latest hospitalization (for deaths not occurring in institutions).

† Voluntary hospitals, which operate under approval of the State Department of Welfare, were not included in the study.

superintendent or proprietor of each hospital requesting his coöperation and explaining the purpose of the study. Each hospital was then contacted by the Department of Health, supplied with a list identifying the deceased included in the study, and appointments scheduled for the abstraction of the case histories.

A simple form was used to collect information; one copy was filled in for each death certificate and another for the corresponding hospital case history. The information was copied from the death certificate exactly as it was originally reported. Supplementary information in regard to causes of death, operations, special laboratory tests obtained through inquiries by burial desk clerks, nosologists, or from special autopsy reports, which is added to the back of the certificate, was not included as a part of the death certificate abstract. All of this work was carefully checked to detect clerical errors.

In preparing the abstracts of hospital case histories, the medical field worker was instructed to "assume that he is the physician called upon to fill out a death certificate and that his knowledge of the deceased is limited to the information found in the hospital case history." Only information available at the time the certificate was filled in was considered in recording the principal and contributory causes of death and using the check list. This information generally consisted of the final discharge diagnoses (excluding autopsy findings made available after the death certificate was executed*), results of laboratory tests, operations, observations during illness, and previous history. Since it was possible that knowledge of the

death certificate information might influence the abstractor in spite of all efforts to use unbiased judgment, the information from the hospital case history was abstracted onto a blank form, which was not collated with the death certificate abstract until each form had been individually processed and coded.

It was not practical or possible to verify the accuracy of all hospital case history abstracts. Moreover, it was recognized in planning the study that the abstractor's personal interpretation of the meaning and importance of conditions would have a significant bearing on his selection of the causes of death. Nevertheless, it was felt desirable to evaluate the completeness of the cause-of-death statements, including the check list data, and the frequency with which non-medical errors (use of incorrect chart, etc.) were committed. Accordingly, a sub-sample of cases from proprietary hospitals was checked by a Department of Health physician. Additional cases from both proprietary and municipal hospitals in which errors appeared possible were checked against the department's rosters of known syphilis and tuberculosis cases, or with responsible physicians in the hospitals in which the deaths occurred. Finally, all cases were reviewed by a physician of the department and questionable cases passed on by a physician of the Statistical Advisory Committee. Among the 7,330 abstracts of hospital case histories, several were adjusted by these methods. While not all errors may have been detected, it was evident that the data were sufficiently accurate for the purposes of the study.

COMPLETENESS AND REPRESENTATIVENESS OF THE DATA

A total of 15,000 cases was selected for study, 6,492 in proprietary hospitals, and 8,508 in municipal hospitals. Preference was given to completion of the work in proprietary hospitals, and

* It is recognized that it may not always have been possible to ascertain whether or not preliminary findings from autopsy were known to the physician at the time he signed the death certificate, especially in municipal hospitals. Analysis of the data, however, reveals no evidence of significant differences in the findings between autopsied and not autopsied cases.

* Coded according to the Manual of the International List of Causes of Death (Fifth Revision) and Joint Causes of Death (Fourth Edition), 1939. † Less than 10 cases.

as soon as the preliminary findings for these data were available, it was decided not to complete the abstraction of case histories in municipal hospitals. As a result, data for 1,678 deaths, or only one-fifth of the cases in municipal hospitals, were obtained for study. The great majority of these completed cases were Manhattan deaths which had been reported on the confidential certificate. The data from municipal hospitals, therefore, can be given little weight in this study. They are included in this report, however, since they appear to be consistent with the findings from proprietary hospitals.*

Of the 6,492 cases which were selected for study in proprietary hospitals, complete data were obtained for 5,652, the hospital charts could not be located for 715, and the charts for the remaining 125 could not be used because they contained insufficient information. According to their distribution by age, sex, color, and cause of death reported on the death certificate, the cases obtained for study from each borough and year comprise a representative sample of the cases originally selected.

MAJOR FINDINGS

The correlation between the primary causes of death as determined from diagnoses in hospital case histories and those determined from statements on death certificates for all 7,330 cases is shown in Table 1. These data indicate the causes to which deaths from selected conditions are generally attributed in New York City vital statistics. They also provide an approximate index of the extent to which these significant diseases are overstated or understated. These indices for the 17 cause-of-death

groups are given in Table 2; column 1 is computed from the data in Table 1, and the other columns from similar tabulations which could not be included in the space allotted for this paper.

The great concentration of cases in the diagonal cells in Table 1 means that there is a very substantial agreement between the diagnoses in hospital case histories and the statements of cause of death on death certificates, and that, judged by these broad cause-of-death groups, disagreement is the exception rather than the rule.

Of the 17 cause-of-death groups studied, only the *respiratory diseases* (33a, 104-114) appear to be significantly overstated in official mortality statistics. They were charged with an excess of 13 per cent in this sample (Table 2). The overreporting of these diseases, primarily the pneumonias, was especially marked among white persons whose deaths were certified by internes in municipal hospitals.

As may be seen from Table 1, many deaths due to respiratory diseases are charged to the cardiovascular-renal diseases and an even greater number due to the latter are incorrectly attributed to the former. The difficulty appears to arise both because of disagreement as to whether the condition is lobar or bronchopneumonia and equally as often from carelessness in stating "lobar" when "lobular" is meant, or vice versa. Since cardiovascular-renal diseases are frequently associated with pneumonia, under the *Joint Cause Manual*, the *International List* assignments for the former conditions are also affected by the proper determining factor as to the form of pneumonia. For example, a cardiovascular-renal condition associated with pneumonia is assigned to the former if lobular, but to the latter if lobar.

In contrast, five conditions (alcoholism, syphilis, puerperal infection, diabetes, and appendicitis) appear to be understated on death records. These

* Contrary to expectation, the data from municipal hospitals reveal greater variations than those from proprietary hospitals. This may result from the fact that quite frequently in municipal hospitals several physicians may attend the same patient, and often the physician who certifies the death may not have been previously connected with the case.

conditions will now be discussed.

Alcoholism (77,124a)—Of all conditions selected for study, alcoholism was most affected by differences between diagnoses in hospital case histories and causes of death stated on death certificates. Of the 54 deaths from alcoholism or alcoholic cirrhosis of the liver, only 23 (43 per cent) were so reported. Sixteen deaths were charged to other diseases of the digestive system, primarily cirrhosis of the liver without mention of alcoholism,* 7 to respiratory diseases, and the other 8 to various other causes. At the same time, 4 deaths supposedly due to other conditions were charged to alcoholism. In this sample, therefore, the official statistics accounted for only one-half of the mortality from alcoholism. This finding is in apparent agreement with the results

of the confidential inquiry in Westchester County, New York, which revealed that approximately three-fifths of the deaths from alcoholism in 1931–1933 were correctly charged.²

Did the confidential method of death certification, introduced in Manhattan in 1939, more accurately depict the mortality from alcoholism than the open method? The pertinent data are shown in Table 3. Since alcoholism is a relatively infrequent cause of death, only a small number of cases fell into the sample and the findings may be influenced by chance fluctuations. However, several facts are worthy of note. Approximately one-half of the deaths attributed to alcoholism were “improperly” reported from proprietary hospitals whether the open or confidential certificate was used. Even municipal hospitals in Manhattan understated this cause of death by one-half in 1939 and 1941. And, as may be seen from Table 2, this was also true for deaths certified by internes. Finally, it should be

* Today many physicians and pathologists question the role of alcohol in the causation of cirrhosis, as such. Thus, even though a patient with cirrhosis had a history of alcohol ingestion, they would prefer to place the etiology in the role of some dietary deficiency.

FIGURE 1

MORTALITY FROM SELECTED CAUSES MANHATTAN COMPARED WITH OTHER BOROUGHES OF NEW YORK CITY*

* By residence; non-residents included in borough of death.

† To maintain comparability between the 1929 and 1938 revisions of the *International List*, deaths prior to 1940 are increased by 9.2 per cent for alcoholism and by 9.1 per cent for syphilis.

noted that, if alcoholism accounted for twice the number of deaths charged to it in official statistics, the recorded number of these deaths should increase significantly when the confidential certificate is used, if the method is more efficient than the open form of certification. Actually, as Figure 1 shows, the trend in Manhattan since 1938 has approximately paralleled the trend in the other boroughs.

Syphilis (30)—About the same extent of agreement between the hospital case history and the death certificate was found for syphilis as for alcoholism. Of the 141 deaths assigned to syphilis according to hospital records, only 66 (47 per cent) were so reported on death certificates. An additional 35 of these deaths were attributed to cardiovascular diseases, 13 to tuberculosis, and 27 to other causes (Table 1). In contrast, syphilis was selected as the primary

cause of death from 11 certificates for which the hospital charts charged the deaths to other conditions. Failure to note on the death certificate that syphilis was successfully treated accounted for some of these differences. Thus, only 55 per cent of the mortality from syphilis was reflected by the official statistics (Table 2). For syphilis as for alcoholism, the data confirm findings previously reported for Westchester County where the figure for syphilis was found to be 51 per cent.² Similar to the findings from that study, syphilis was more accurately reported as the primary cause of death for men than for women; in this study the ratio was 0.58 among white males and only 0.40 among white females.

Syphilis appears to have been more completely reported from proprietary hospitals in Manhattan during 1939 and 1941 than during 1937–1938 (Table 4):

charged to various other conditions. In contrast, the deaths of 22 persons were allocated to diabetes in disagreement with the facts recorded in their hospital case histories (Table 1). For the cases included in this study, therefore, only 86 per cent of the mortality from diabetes was stated in the official statistics (Table 2).

In view of the fact that diabetes was

less completely reported from proprietary than from municipal hospitals, and that deaths certified by attending physicians were least accurately recorded, one might expect an improvement with the use of the confidential certificate. No such evidence, however, is disclosed by the available data. As may be seen from Table 6, 78 per cent of the deaths due to diabetes in Manhattan proprie-

OTHER FINDINGS

Tuberculosis (13-22)—It does not appear probable from the data collected for this study that tuberculosis has been understated in the New York City mortality statistics for recent years. For every 100 deaths from tuberculosis according to hospital case histories, there were 101 assigned to the condition in the official death records (Tables 1 and 2). These findings are in apparent agreement with those obtained in the study in Williamson County, Tennessee.¹⁶

Although tuberculosis was not understated as the primary cause of death for the cases studied, its occurrence as a contributory cause was not completely recorded. This fact may be noted from a vertical comparison of the data in Table 8. For example, in Manhattan proprietary hospitals during 1937-1938, the extent of agreement was 100 per cent for tuberculosis as the primary cause of death, but only 90 per cent

for the condition as the primary or contributory cause. Regardless of the criterion used, however, there are no indications that tuberculosis was more efficiently recorded on the confidential than on the open certificate. The mortality statistics for New York City confirm this fact (Figure 1).

Cancer (45-55)—Of the seven conditions considered likely to be affected by confidential certification, cancer is both the most important and apparently the most completely reported. A study of deaths which occurred in Massachusetts in 1932¹⁷ revealed that approximately 6 per cent of the mortality from cancer was underreported on death certificates; 11 per cent of the cases were "missed" at the same time that 5 per cent were "overdiagnosed." More recently, from a survey of ten urban areas in 1937-1939, the U. S. Public Health Service reported that possibly only 5 per cent of the mortality from cancer was assigned to non-

malignant causes on death certificates.¹⁸

While the procedures followed are not similar, our data confirm these findings. Of 1,229 deaths from cancer, 1,176, or 96 per cent, were "properly" certified on death records. The other 53 deaths were charged to various other conditions (Table 1). Offsetting these "misses," 60 deaths were attributed to cancer on death records in disagreement with the facts available in hospital charts. For the cases included in this study, therefore, the official mortality statistics accurately reflected the extent of the mortality from cancer. This was true for deaths which occurred in proprietary hospitals as well as those reported from municipal hospitals (Table 2).

In view of the above, it is highly improbable that cancer is understated in the mortality statistics for New York City. It would not be expected, therefore, that the confidential method would have any effect on the accuracy of these statistics. This fact is confirmed by the data in Table 9, and the trends in the mortality from cancer shown in Figure 1.

Mental Disease—Because of the small number of cases, mental disease (84) as a primary cause of death is included with the "All Others" group in Tables 1 and 2. Analysis of the extent to which mental diseases (84, 162a, pt. 77b, 150b, 30b) are mentioned on death certificates, whether or not the conditions contributed to death, reveals no

evidence that they were more completely recorded on the confidential than on the open certificate.

External Causes (78, 79, 163-198)—Among the 7,330 deaths studied, 17 cases were found in which an external cause appeared in the hospital case history but was not reported on the death certificate. Of these cases, 12 deaths should have been charged to the external cause, and 5 to other conditions. As may be seen from Table 1, one-half of the 12 deaths from external causes were charged to cardiovascular-renal diseases on death certificates, 2 to respiratory diseases, and 1 to each of four different conditions. Evaluation of these cases indicates that most if not all of these differences involve intentional avoidance of medical examiner action. As such, it is doubtful whether any form of reporting can be expected to eliminate these discrepancies.

Operations Performed—The completeness with which operations are reported on death certificates has a major effect on the accuracy of mortality statistics. It is pertinent, therefore, to ascertain whether operations were more completely reported on the confidential than on the open certificate.

Analysis of the data for 5,606 white decedents from proprietary hospitals reveals that operations had been performed on 2,147, or 38.3 per cent, of these patients. Of these, 2,097, or almost 98 per cent, were reported on official death records. While the fre-

quency of operations declined from 41.3 per cent in 1937 to 34.8 per cent in 1941, there was a slight improvement in reporting, from 96.6 per cent in 1937 to 98.2 per cent in 1941. This improvement, however, occurred in proprietary hospitals in boroughs other than Manhattan. Judged by proprietary hospital deaths, therefore, the confidential method did not result in more accurate reporting of operations.

DISCUSSION

When, about the year 1891, the confidential system of reporting was put into use in certain cantons of Switzerland, the number of reported deaths from syphilis was nearly doubled. Accordingly, the system was adopted and has been used throughout that country since January 1, 1901.¹⁹ On the basis of this experience, it was expected that there would be a marked increase in the reported mortality from syphilis, as well as from several other diseases, following the introduction of the confidential system to New York City. In the first year of its trial in Manhattan, the confidential report apparently had increased the accuracy with which the mortality from syphilis was reported. Since that time, however, the parallel trends in the mortality from the disease,

both in Manhattan and in the other boroughs of the city (Figure 1), have made it appear more probable that the rise, which was recorded in Manhattan from 1938 to 1939, was chiefly if not entirely a normal fluctuation.

The use of the confidential report was extended to the other four boroughs of the city on January 1, 1947. If the system proved effective, we should expect an increase in the mortality from alcoholism, syphilis, etc.; in these boroughs, but not in Manhattan, where no change in method of reporting occurred. The recorded mortality data for the first 11 months of 1947 compared with the same period of 1946, for seven conditions considered significant to confidential certification, are shown in Table 10. There is no evidence from those data of any changes which may be attributed to the system of reporting. Therefore, it may be concluded that, to date, the confidential report has had no significant effect on the accuracy of mortality statistics in New York City.

No method of reporting, of itself, can be expected to eliminate all of the factors which affect the accuracy of mortality statistics. In 1938, Dr. Halbert L. Dunn stated that "the errors in cause of death due to carelessness on the part of the physician in filling out the

TABLE 10

death certificate are probably fully as numerous as those arising from his desire for a confidential record. . . ."¹¹ From this study, one might add that simple ignorance of the rules of certification and lack of understanding of the mechanisms of death also have a greater bearing on the information that is recorded than does the method of reporting. Moreover, there are no indications that better statistics have resulted from the use of the confidential method.

How then may we effectively and efficiently improve the accuracy of mortality statistics? This is a problem of major importance which confronts the consumer of vital statistics. Together with the instructor in the medical school, he must devise a means of impressing the attending physician with the importance of his responsibility in reporting causes of death. This should involve careful perusal of the patient's history chart to determine the factors which caused and contributed to death, and entry of the cause-of-death statement on the certificate with sufficient accuracy and care so as to reflect his conclusions.* Some improvement could also be effected by a change in policy, in local health departments, from paper check-up by death certification clerks to a consultative service which the physician could call *before* he certifies the cause of death. This would enable the physician, who has had few deaths in

his own practice, to obtain the advice of one who has had practical experience with a great many cases as to the terminology and definition of causal mechanisms involved in a particular case.

The physician's unwillingness to record the causes of death to the best of his knowledge and belief is apparently of secondary importance to other factors which affect the accuracy of mortality statistics. Judged by the findings from this study, the confidential report does not improve the accuracy of diagnoses which reflect on the memory of the deceased. Apparently such improvement can be effected only through intensive educational campaigns which impress both the medical profession and the public with the fact that the development of medical knowledge, and the ability to combat disease, are dependent upon complete and accurate statistics. The campaigns against tuberculosis and cancer have removed many of the barriers of fear and superstition concerning these conditions and have thus been a factor in the present state of completeness with which they are recorded on death certificates. The current campaign against the venereal diseases has already effected a reduction in the inaccuracy of these mortality statistics. In the near future, as the campaign becomes more successful, the public will be completely impressed with the fact that the disease can be conquered. At that time, it may be expected that the true extent of the mortality from syphilis will be reflected by official statistics. Undoubtedly, most persons in this country prefer to face the facts openly and squarely, and will not intentionally withhold significant information once they are made cognizant of its value and importance.

SUMMARY

1. A confidential method of reporting causes of death, for deaths due to natural causes, has been used in the borough of Manhattan since

*The importance of the above cannot be overemphasized. In New York City, for example, more than one-half of the deaths are certified from institutions where more than one practitioner is in attendance. Frequently, these institutions find it necessary to execute a death certificate at a time when no physician who attended the patient is available. Even when one of the physicians is available, it is not possible for him to be able to fill out the death certificate without reference to the case history.

The situation is quite similar for an additional one-fifth of the deaths in New York City, which are certified by the medical examiner's office. In addition to the information obtained from the hospital or private physician, the completed history for these cases may contain extensive notes resulting from the examiner's investigation. All of this information must be carefully considered both from the medical examiner's and the vital statistician's point of view when the death certificate is prepared.

January 1, 1939, and in all five boroughs of New York City since January 1, 1947.

2. In 1943-1944, a study was made of 5,652 deaths which were certified from proprietary hospitals in 1937-1939 and 1941, and of 1,678 deaths which were certified from selected municipal hospitals in January and February of those years.

3. Judged by diagnoses abstracted from hospital case histories, five conditions were found to be understated on death certificates. The official statistics for these 7,330 persons accounted for only 50 per cent of the mortality from alcoholism, 55 per cent for syphilis, 74 per cent for puerperal infection, 86 per cent for diabetes, and 87 per cent for appendicitis. Tuberculosis and cancer were found not to be understated.

4. There are no indications from the data that better statistics have resulted from the use of the confidential death certificate.

5. The trends in the recorded mortality in Manhattan, while the confidential report was used, closely paralleled those for the boroughs which used the open certificate. Comparative mortality data for the first 11 months of 1946 and 1947 also reveal no changes which might be attributed to the use of the confidential report in all boroughs of the city since January 1, 1947.

NOTE: Special acknowledgment is made to Kurt Pohlen, Ph.D., employed under a grant from the New York Foundation, for his technical assistance, especially for his painstaking and diligent efforts in abstracting the diagnoses and related information from the original hospital records.

Acknowledgment is also made to Drs. Allan Hurst, Alfred Koerner, and Oma H. Price of the Department of Health, and to the hospital superintendents, proprietors, record librarians, and many other persons whose assistance and coöperation helped to make the study possible.

The author is grateful for helpful suggestions in the preparation of this paper to Dr. Louis I. Dublin, Second Vice-President and Statistician, and Herbert H. Marks, Manager, Insurance Medical Statistics, both of the Metropolitan Life Insurance Company, and to many of the persons already mentioned.

The opinions expressed herein are those of the author and do not necessarily reflect the views of the New York City Department of Health, the members of the Statistical Advisory Committee, nor of the other persons to whom acknowledgment has been made.

Selecting Public Health Personnel Through Examining Processes

Gleanings from the Conference of Health Officers and
Merit System Supervisors *

DOROTHY DEMING, R.N., F.A.P.H.A.

Merit System Service, American Public Health Association, New York, N. Y.

THIS conference, which consisted of an interchange of experiences in the use of various examining processes for the selection of public health personnel, was attended by health department and merit system representatives. Discussion, led by Dan S. Moore, State Director of Personnel, Louisiana Civil Service Commission, was informal, and focused for the most part on the three currently employed methods of selecting personnel under merit system regulations: the rating of training and experience, the written test, and the oral interview, with brief consideration of the weights given each in relation to the level of position under scrutiny.

While there were no formal recommendations arrived at during this conference—such was not its purpose—some of the comments and conclusions of the group are of such timely interest to administrators as to warrant recording.

THE ORAL INTERVIEW

There are two major purposes for which oral interviews are used: to sample the candidate's knowledge of the field, and to evaluate such factors as his personality, appearance, and ability to think and speak logically and clearly. It was suggested that a written examination properly constructed to test a can-

didate's knowledge, yields a far more precise measure than does the oral interview. The group agreed, however, that an oral interview to evaluate appearance and personality is especially important in selecting public health personnel because so many of the staff must meet and deal daily with the public. No administrator present was willing to appoint a public health physician, nurse, or engineer without a personal interview, and a board of oral interview serves as a preliminary screening of candidates for such interviews.

The objections to oral tests that were mentioned included: (1) a misconception, occasionally held by candidates, to the effect that interviews are "fixed" in advance; (2) the difficulty in scoring objectively and weighting appropriately the factors to be measured by the interview; (3) the frequent lack of a verbatim record of the interview which makes it difficult to prove the basis on which the individual interviewers made their judgments. Even with these drawbacks, however, the majority seemed to feel that the oral interview is a very necessary step in selection, and eliminates those obviously unsuited from a personality standpoint. No one would give it up.

THE RATING OF TRAINING AND EXPERIENCE

While no one present could offer a truly valid and workable method of eval-

* Presented at the Seventy-fifth Annual Meeting of the American Public Health Association in Atlantic City, N. J., October 6, 1947.

uating experience and training of professional public health personnel, all agreed that such rating is very essential. It was pointed out that its value, and therefore the weight assigned to this rating, increases with the importance of the position. For example: a public health nursing supervisor's training and experience bear a more direct relation to her potential ability to do the job well than the training and experience of a graduate nurse who will serve as an assistant to a public health nurse in a clinic. In fact, several health officers present thought that the rating of training and experience, plus the oral interview were the only tools needed or wanted in their states in selecting public health physicians.

THE WRITTEN EXAMINATION

The group devoted considerable time to discussing the pros and cons of requiring written examinations of professional personnel.

Those in favor of making the written examination an intrinsic part of the selective procedure offered in support of their opinion their belief that the written test presents:

1. Clearcut, indisputable evidence with regard to a candidate's knowledge of facts, and, if the right type of questions are used, provides an excellent measure of his capacity for exercising sound judgment.

2. The most reliable means we have to date for *ranking* candidates objectively. Several merit system supervisors and health officers remarked on the success with which the examinations prepared by the Merit System Service differentiated between the well prepared and less well prepared candidates in their states.

Many of those present indicated that they would like to use the objective type of written tests for all positions, but stressed their inability to persuade some of the professional groups to take examinations, because these groups:

1. Resent taking still another examination when they are already graduates of medical and nursing schools and licensed to practise,

2. Dislike—and this is easily understandable—finding that in spite of years of experience, they occasionally make scores lower than candidates with far less experience.

3. Feel that an objective test measures theoretical knowledge only.

It was also pointed out that one very bad factor in requiring a written test is the hardship worked on the candidate who is ill on the day of examination and who must then wait until another examination is held before being placed on the register.

A few persons present went so far as to say that professional people who have passed licensing examinations should be exempt from written tests and be judged on a rating of their training and experience, and by an oral interview. Merit system supervisors immediately pointed out that while this procedure may work when only 3 or 4 candidates are applying, a finer, more objective screening must be devised when 30 or 40 candidates are being ranked. With the best of efforts, the rating of training which has taken place in 30 or 40 different institutions all using different grading methods is difficult, while an evaluation of experiences which have occurred under as many as 100 employers each of whom offers a subjective opinion of the candidate's performance, leaves the scorer hopelessly at sea.

All were agreed, however, that reluctance to take written tests will probably be overcome when the candidates find the examinations are professionally acceptable and appropriate to the level of duties of the job. Such an examination can be compiled only if the specifications are good—that is, give complete descriptions of the requirements for, and of, the job. There is much room for improvement in many of the present job specifications.

WEIGHTING THE SELECTIVE PROCESSES

The discussion then turned to weighting the three selective processes: the oral interview, rating of training and expe-

rience, and written tests. The consensus seemed to be that the written tests for entering positions should receive very heavy weighting; that the oral interview should carry least weight of the three, perhaps 20-30 per cent; and that the rating of training and experience should carry a generous weight for "upper bracket" administrative positions, much less for first level jobs.

In conclusion, Mr. Moore summed up the situation by saying

The establishment of a minimum qualification for admission to practise a profession, does not, in and of itself, eliminate from merit system selection those people who are

not fitted to carry the specialized job. If some other device is not used, the appointing authority may find himself called on to choose the best of three undesirables. Written objective-type tests, properly constructed according to adequate job specifications, are suggested as appropriate and desirable instruments for ranking candidates

He reminded the audience that the Merit System Service of the A.P.H.A. is interested in all steps in selecting personnel. It can suggest the names of persons to serve on oral interviewing boards, and as advisers for assisting with the rating of training and experience, as well as supply the written objective-type tests under discussion

Beginnings of a Mental Health Program in a State and Local Department of Health*

KENT A. ZIMMERMAN, M.D.

Consultant for Mental Health, State Department of Public Health, San Francisco, Calif.

HEALTH officers in general recognize that a pressing need in their communities is the rapid development and expansion of mental health programs. Most feel that the community pressure is for the development of treatment clinics, and many people in health departments assume that that is the only kind of a program they can justifiably sponsor. Child guidance clinics and psychiatric clinics would probably be established by the thousands, almost overnight, if it were not for two very frustrating considerations, the lack of funds to operate a clinic and, even more serious, the inadequacy of well trained personnel. Many individuals, therefore, feel bewildered, and some discouraged when they find themselves blocked by these frustrations. In general, few people seem to see the work that is being done daily in the well baby, prenatal, tuberculosis, and venereal disease clinics, and in home visiting and family health counseling as being a very important opportunity for the promotion of mental health.

The reasons for such an attitude are perfectly justifiable. The usual well trained physician and nurse today do not think of themselves as capable of handling even simple emotional prob-

lems. Their professional education often did not give them this concept, and psychiatry itself has until very recently remained isolated from the rest of medicine. Consequently the general attitude in the majority of medical and nursing schools which seemed to be conveyed to the students, was that when there were problems of medical practice which related to feelings and attitudes, it was important to be aware of these, but, if possible, they should be left alone. This is one important reason why most doctors and nurses feel insecure when confronted with the emotions that accompany illness and convalescence. In many professional individuals there is also a lack of awareness of the importance of the emotional relationships that exist between doctor and nurse and patient, and their influence on both doctor and patient in everyday medical practice.

A growing number of people interested in mental health problems are coming to feel that a practical approach to the problem of meeting the mental health needs of communities could be made through professional workers already giving service to the communities. One of the most important of these groups is that of the health workers, who in company with school teachers, social workers, probation officers, and physicians in private practice, are concerned with helping people handle their problems and educating them toward

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

the self-responsibility of keeping happy and well.

WHAT ARE THE PROBLEMS?

In coöperation with the Commonwealth Fund, the California State Department of Public Health undertook a project to ascertain what kind of program might be necessary to promote incorporation of mental health principles as part of public health practice. In late 1946, two physicians, with training in pediatrics and psychiatry and some experience in public health, joined the staff of the State Department of Public Health. These physicians were myself and Dr. Martha MacDonald. Dr. MacDonald worked with us for three months and then, unfortunately for us, resigned to do purely clinical psychiatric work. The first thing we did was to make a study of the State Department of Public Health and three local departments of health in the San Francisco Bay area. We needed to learn something about the following:

1. Attitudes of staffs about psychiatry and mental hygiene
2. How the staffs felt mental hygiene and psychiatry might help with their work
3. What did the staffs feel capable of doing
4. What did staff members lack which prevented them from becoming more effective in promoting the emotional well-being of their patients
5. How this could be supplied to them within the limitations of time for training and the tremendous work load which each department and staff member faced

A brief description of our findings and impressions pertinent to this discussion give some of the answers to the above questions. A large number of public health workers are eager for staff training in mental health concepts. However, any training program has to take into consideration the fact that because of the extremely heavy work load

and the shortage of personnel, administrators are reluctant to give long periods of time to such training. At the same time, administrators feel the desire of their staffs for training in this field. They are beginning to understand that a high turnover of personnel is often the result of the blocking of professional individuals in their growth by overwork and the lack of opportunity for instruction. Highly trained personnel for education of local staffs cannot in general be attracted to local staffs because of the low salary scales. Local departments of health, therefore, are turning more and more to state departments of health for consultation, planning and financing of training programs.

Concepts about the training of local personnel are limited. Many health officers and nursing supervisors feel that a course of lectures on mental hygiene will meet the needs, and their thinking about education often stops here. Too infrequently do they see that a program needs to be planned so as to follow up in local public health practice what was covered in the lectures. One reason for this is that they feel that they need the mental hygiene expert to perform this task and rarely think of using people in their own communities who could supply another viewpoint and the discipline of another training such as school teachers, probation officers, social workers, etc.

In the majority of local health departments, where there are often only one or two full-time physicians, the backbone of clinical service is the public health nursing staff. The physicians who usually attend the clinics come for, perhaps, one afternoon a week and perform their duties and leave the health department alone the rest of the time. In the main, the physician performs the mechanical part of medical practice and when there is an important and emotionally-laden decision about the course of activities of an individual and his fam-

ily in relation to illness, this task is usually given to the nurse to handle. Even with the patient who has no major problem at the moment, it is the nurse in the clinic who often takes the history, explains the doctor's orders, or sees the patient functioning as part of the family. It should be no surprise, therefore, that the nurse is avidly seeking for information and guidance on normal emotional growth of individuals and their families. The nurses are the ones who have to support the insecure mother of the new baby, help the adult with tuberculosis to accept sanatorium care, get the patient with venereal disease to see responsibility in coming for treatment, etc. Yet the nurse is all the more insecure, because her professional training and background have often been of an authoritarian nature, and she finds that this approach to the emotional problems such as she handles is rarely successful. Furthermore, as is also the case with physicians, she has often had no training whatever in the science and art of interviewing which both professions find again and again in their practice is the very thing they need most.

Another striking thing about many health departments is their utter lack of awareness of what other community agencies in their community are doing. Again, the person who interrelated these activities in the community was generally the public health nurse who, in her health work with families, needed to work with the social worker and the school teacher and sometimes the probation officer. However, the problem was mainly that the health department was so overwhelmed with work, as are the other community agencies, that its staff could rarely lift its eyes beyond its own confines and see itself as an important element in a total community picture of community services. This increased, therefore, the frustration of many sincere and conscientious individ-

uals who felt discouraged that there was so little they could do in meeting the emotional needs of their patients and families. This seemed to be because they thought in terms mostly of their own services, and, because of their lack of knowledge of the total community facilities, failed often to see the real importance of their own contribution to the patient.

Practically all the physicians who worked in the clinics felt a need for more knowledge of the normal individual, especially as to his growth and development, his reactions to illness, and his role in the doctor-patient relationship. Many physicians thought that this would help them in their practice as well as in their dealings with people everywhere. But also, it must be confessed, many physicians saw no particular reason for this since they were functioning quite successfully in their practices; and many felt that most simple emotional problems should be referred immediately to the psychiatrist.

Nurses stated they wanted more instruction about the normal emotions in children and adults and instruction on the techniques of interviewing. Occasionally an intuitive individual recognized that her own emotions and attitudes seemed to interfere or help in the treatment of some of her patients and would ask if some teaching could not be offered on this subject.

In summary it might be said that health workers are:

1. Eager for what psychiatry can offer them.
2. Belittle the potentially important mental health role they could play; feel they need the expert before anything can be done.
3. Feel inadequate in knowledge about the normal emotional behavior of children and adults. This is practically like saying that they want more confidence in knowing what human behavior really is.
4. Need more understanding of the emotional structure of the doctor-patient and nurse-patient relationship.
5. Want some instruction in interviewing and counseling.

In this local health department I worked at first as pediatrician in a typical well baby clinic. Our plan was to have the nurses of the staff rotate through this clinic. In addition to observing, each nurse was to select two or three patients or families who represented a problem in management or were of especial interest to her. The nurse was to keep good notes on these patients, especially of the interviews. At the end of each clinic session these patients were discussed from the standpoint of emotional change in both patient and nurse, or what some psychiatrists and psychiatric social workers call "movement" in the emotional interrelationship as it developed and waned. The object here was to simulate an approach to the case work situation which the learning social worker goes through in her training. In this way it is felt that some attention can be given to the nurse and her feelings so that she begins to learn and accept certain approaches which she as a personality can use in dealing with patients which affect the patients either positively or negatively in relation to their medical care. This experience, going on concomitantly with the lecture material given during the weekly nurses' staff meetings, required the integration of much more of the material into the nurse's personality. Likewise it provided a method of controlled growth of the individual in understanding the emotions of others and also those of herself in relation to her patients. The practical difficulty with this scheme was that we could not reach all the nurses on the staff with such personalized teaching.

A new scheme is now being developed. The health officer and the supervisor of nurses arranged that I attend a special well baby clinic to which all the nurses could refer two or three families from her district. We could thus have at least two nurses attend with their families at each session, and in a matter

of two to three weeks each nurse on the staff would have the opportunity to talk about how she felt about her patients and how she thought her patients felt about her.

I visit also the tuberculosis, crippled children screening clinic, rheumatic fever, and venereal disease clinics. This is more a consultation service discussing with the physicians and nurses those patients who refuse treatment, refuse hospital or sanatorium care, who become hostile in attitude, and those whose anxieties produce further symptoms and the like. Our policy here is to support and guide the nurse and the physician so that they handle these patient problems themselves rather than label the patient uncoöperative or refer him to the law officer or psychiatrist, if any is available.

Under the leadership of the health officer and the director of maternal and child health of the Richmond Health Department, the pediatricians in practice who attend the well baby clinics for the health department are considering meeting for a weekly luncheon at which the progress of our program will be followed and some discussions will be held on the mental health implications of office practice.

Along with this demonstration in a local health department it is contemplated that in coöperation with the Child Development Center of the Children's Hospital of the East Bay, the State Department of Public Health should also set up an experimental experience to see whether we can in another way supply some of the needs that nurses and physicians in public health, and medicine in general, do not get in their professional training. One of the great lacks for all physicians and nurses in their training has been an opportunity to understand and be with the normal child and get acquainted with the fact that he has emotions of hostility and anger which he must learn to in-

Volunteer Participation in Community Health in Hawaii*

RAYMOND GEORGE NEBELUNG, DR.P.H.

*Executive Director, Public Health Committee
Chamber of Commerce, Honolulu, T. H.*

ANY health problem, no matter how complicated, can be handled effectively if it is broken down into its different aspects. These individual problems can then be dealt with independently; but an integrated overall plan is essential so that the various programs will strengthen each other and eventually lead to unified community action.

For the past two and one-half years we have been building an organization for this purpose in Honolulu. The program is still in its developmental stages but sufficient progress has been made to indicate that lay persons not only are interested but are eager to assume responsibility in health activities under professional direction. Volunteer workers are being utilized with good results. Our first step was to study and to evaluate existing health programs in terms of community needs. Then it was possible to work out policies and procedures on the basis of available data and the coöperative concern of community groups. The second step was to make the facts known and to keep them before the public through a sustained and constructive educational program that will bring about action in these matters. Both lay and professional groups have participated in all phases of the work. We are endeavoring to make community needs better understood; and to secure

services more broadly conceived, adequately financed and administered.

The most difficult part of the demonstration has been the educational phase because it requires a sustained effort in which both lay and professional persons must participate if public interest is to be maintained. Furthermore, it necessitates a high quality of leadership, individual initiative, and a lot of time on the part of both groups.

The instrument which we are using to advantage to achieve our objective is a health council. Current membership in this activity includes 56 organizations, of which 35 per cent are civic organizations, 25 per cent professional groups, 22 per cent voluntary agencies, and 18 per cent official health agencies. The governing board consists of the council chairman, vice chairman, secretary, the chairmen of the three standing committees, two members elected by the council, and the two delegates representing the Public Health Committee of the Chamber of Commerce of Honolulu. Council expenditures are borne by the latter organization as a part of its contribution in the interests of promoting better community health. The professional personnel of the Public Health Committee function as the technical staff for the council. Planning and co-ordination are brought about through the program, education, and legislative committees, headed by lay and professional volunteers. Committee members are selected by each chairman, giv-

* Presented before the Public Health Education Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 10, 1947.

ing due consideration to all racial groups and organizations. Because these are working committees, emphasis is placed upon utilizing lay individuals as far as possible and making use of professional health personnel in a consultant capacity. Services of the latter are best used in planning because they usually do not have sufficient time to undertake the all-important follow-up activities. Besides, placing responsibility on lay volunteers gives them an incentive to demonstrate leadership and is a motivating force in overcoming public inertia.

Bi-monthly meetings, and special sessions as required, are held by the council. Programs are planned in cooperation with the various groups on the basis of interests and needs. This organization has provided a mechanism for discussing in a democratic manner health problems that have community concern. Also it has made possible the machinery with which to carry on follow-up activities of an educational and legislative nature which will enable us to deal more effectively with these problems.

A number of tangible results have already been achieved. They include establishing a full-time professorship in health education at the University of Hawaii, setting up a school of practical nursing under the auspices of the Vocational Division of the Territorial Department of Public Instruction, inaugurating outpatient clinic facilities in two local hospitals, sponsoring a Hawaii branch of the National Society for Crippled Children and Adults, and preparing an exhibit and booklet *The Health Story in Hawaii*.

Hawaii's health story merits special consideration because it is unique in our experience. Its purpose was twofold: to compile and present in a readable and interesting manner factual information on health in Hawaii; and to acquaint people throughout the Territory and on the mainland with health activities in

the islands. The project was sponsored by the Public Health Committee of the Chamber of Commerce of Honolulu in cooperation with the Oahu Health Council. The former organization initiated the idea and subsidized the costs entailed in its preparation.

The chairman of the Community Education Committee of the Oahu Health Council headed the special exhibit committee. Other members included representatives of the Public Health Committee of the Chamber of Commerce of Honolulu and its staff, Territorial Medical Society, Territorial Board of Health, Hawaii Visitors' Bureau, and Holst and Cummings advertising agency. The first problem which confronted them was how to portray the desired overall picture of health work in the Territory. It was finally decided to prepare a small booklet of approximately one hundred pages with photographs and descriptive copy.* It was also agreed that the content should feature health programs rather than the specialized work of individual agencies because it seemed more logical to tell what is being done rather than who is doing it.

The first step was the preparation of an outline allocating a certain percentage of space to each activity. Then a script was written showing why the percentages were made and outlining the points to be covered in each picture and page of copy. This material was circulated to each health council member and to other interested persons throughout the Territory. A revised outline embracing the suggestions and criticisms received was then drawn up, and work schedules were made out for photography and final copy. Fourteen agencies and individuals contributed photographs; sixteen organizations provided consultant services and other materials.

* *The Health Story in Hawaii*, Public Health Committee of the Chamber of Commerce of Honolulu, 1947.

The other phase of the project consisted of the preparation of a health exhibit which features fourteen photo murals mounted on a mechanical page turner. Hawaiian scenes form the background. The exhibit was prepared for display in the Scientific Exhibit Section of the 75th annual meeting of the American Public Health Association.

In the development of our program we have been motivated by the desire to obtain greater interest and more participation in community health work on the part of the general public. Satisfactory progress can be achieved only through dynamic leadership and the support and utilization of professional and lay volunteer personnel.

Cutter Recalls All Dextrose Solutions

Dr. R. K. Cutter, President of Cutter Laboratories, on May 6 telegraphed the following information for readers of the *Journal*:

"Contamination has been found in another and entirely different glucose solution, dextrose 10 per cent in Ringers. The company is coöperating with the Food and Drug Administration, and is requesting the assistance of health departments throughout the country, in immediately recalling from hospitals Cutter's entire line of dextrose and other solutions for mass intravenous injection. Company officials believe that discovery of this new contamination makes questionable the use of any product pro-

duced in their intravenous solutions department until this entire contamination difficulty is solved. The other products produced in this department are concentrated dextrose, distilled water, sodium citrate, normal saline solutions in 50 and 100 cc. bottles, as well as all flasks supplied by Cutter for community blood and plasma banks.

"The reason for this contamination is still unknown, and until they have the positive answer, Cutter feel that this is the only step that can be taken in the interest of public safety. In the meantime, arrangements are being made to supply hospitals with solutions of other manufacturers."

further observation and control are more certain. The school group, from 7 to 14 years of age inclusive, comprises 2,145,000 individuals, equally divided between the two sexes. As a group for investigation, it represents 21.4 per cent of the total Colombian population. Its distribution among the 14 departments of the Republic fluctuates between 22.1 per cent and 19.6 per cent according to information compiled by the Contraloría General de la República. From January, 1945, until July 31, 1947, there were examined a total of 140,163 school children throughout the 14 departments. The number of those children affected by simple goiter was 79,505 or an incidence of 56.5 per cent.*

The criteria for the diagnosis and classification of simple goiter in reference to form, size, and consistency, were established in a unified fashion from the initiation of the project. All examination of persons and the registration of the data were in charge of a special medical commission created for that purpose.

2. With the data obtained from the survey there was made a national map of the distribution of simple goiter by departments.

Mere observation of this map permits full appreciation of the high incidence of simple goiter (from 37 to 81 per cent) in the departments in the interior of the country. This is in marked contrast to the low incidence (less than 10 per cent) in the coastal areas along the Atlantic and Pacific.

The great difference between the two percentages is highly significant. It is apparently explained by the greater consumption of iodine by the inhabitants of the coastal regions. That iodine is obtained from the atmosphere itself and

from foods of marine origin (including sea salt).

3. Based on the available historical data and the partial results of the survey on the incidence and distribution of simple goiter in Colombia, two very important premises may be established:

First, in some localities, formerly similarly affected by goiter, this endemia has been gradually disappearing, apparently as a result of better nutrition and the hygienic water supply for drinking purposes established for its inhabitants.

Second, for the last thirty years the endemia of simple goiter has been invading areas formerly untouched by it, such as—the Departments of Caldas and Antioquia. This has been due to the fact that the regional consumption of salt from iodized sources, has gradually been almost completely replaced by the use of salt from the large mines near Bogotá. The salt from these mines is extremely low in iodine content but it is cheaper, since it is exploited on a large scale and it is easily distributed to various centers of consumption due to the development of means of transportation throughout the country.

4. a. Simple goiter and drinking water—

The popular belief predominates in Colombia that the drinking of "hard water" is the cause of simple goiter.

In conjunction with the census of simple goiter, an attempt has been made to establish an association or correlation between these two phenomena; 209 water samples having been taken from 293 places included in the census.

The conclusions have been the following:

First, in places with "soft water" (up to 75 p.p.m.) and "semi-hard water" (up to 150 p.p.m.) the incidence of simple goiter fluctuates between 7 and 90 per cent.

Second, in localities where there is "hard water" or "very hard water" (more than 150 p.p.m.) the incidence

* These data include all the sizes of goiter (+ to ++++). If there are excluded the cases of (+), considered as transitory or "physiological," the incidence is reduced from 56.5 per cent to 35 per cent.

of simple goiter is always high, i.e., more than 45 per cent.

b. Simple goiter and climate—

There exists no correlation between these two phenomena. Simple goiter is distributed in an equal manner between the various climatic areas. (Cold climate—more than 6,000 feet above the sea level in altitude; temperate—between 2,500 and 6,000 feet above the sea level; and hot climate—less than 2,500 feet.) There is, however, a higher frequency in climates where anquilostomiasis or hookworm predominates.

c. Simple goiter and cretinism—

In some regions of Colombia, where simple goiter endemia is of long duration, there may be noted defects in physical development (stature shorter than that of the average) and abnormalities in mental development on a scale varying from the mentally retarded and "slow" to the cretin and the idiot.

5. Prophylactic Measures—The historical antecedents of the simple goiter endemia in Colombia, the determining factors in its invasion and extension into some regions, the significant difference between the incidence of the endemia in the interior and the coastal regions of the country—all lead one to consider the relative scarcity of iodine as the principal etiological factor in the incidence of simple goiter in Colombia. This, of course, does not exclude the effects of other contributory elements.

On the basis of this etiological premise, the Department of Nutrition proceeded to search for an adequate manner of furnishing a supplementary source of iodine—as a prophylactic measure against simple goiter. It was proposed to incorporate this supplementary iodine into ordinary kitchen salt for use by the inhabitants of the interior of the country.

As the first step in this procedure, the average daily consumption of salt per

capita was determined. This is 15 gm. Then, the optimum iodine content of the salt was calculated to be 4 mg. per 100 gm.

Samples of the salt, with a natural iodine content, from the old mines were analyzed but though the original iodine content was acceptable, the production capacity for the desired consumption was inadequate.

Samples were also analyzed for iodine content of the marine salt and the salt from the mines near Bogotá. The iodine content was almost equal.

It was then planned to iodize and stabilize the marine salt, but the project was abandoned because of technical difficulties and administrative problems (collapse of the production of the mines, social problems with labor, cost of transportation, etc.).

6. Artificial iodization of salt—

It was finally decided to iodize artificially and stabilize the salt from the mines of Zipaquirá, Nemocón and Sesquilé, situated almost in the geographical center of Colombia.

The manufacture of salt in powdered form from these mines follows a process which consists essentially of the following: (1) extract the mineral from the mines, (2) dissolve it in sweet water, (3) let it be purified and concentrated in a solution called "salmuera" up to 28-30 per cent salt, (4) evaporate the salt solution in containers of iron at a temperature of 98-100° C., (5) separate into precipitated salt, (6) permit to dry and transport for wholesale distribution in burlap sacks (retail sales per pound in paper sacks or wrapped in vegetable leaves).

At the present time there is manufactured and consumed a quantity of 100,000 tons of land salt per annum, destined for human use and for that of animals.

The method of artificial iodization tried out and adopted consists in adding to the salt solution—before it is placed in the iron caldrons—the mixture of

iodine and chemical stabilizing substances. This method does not require special machinery, obtains a uniform distribution of iodine throughout the salt, and results in being both simple in procedure and economic in cost. The stability of the iodine in the iodized salt is checked by samples submitted to various temperature and humidity conditions in cold, temperate, and hot climates, and in containers of ordinary paper. The loss of iodine content fluctuates between 3 and 4.5 per cent of the original content, after from 8 to 14 months subsequent to the time of the manufacture of the salt.

There is already information to determine the most adequate composition of the iodine mixture necessary in order to obtain a stabilized artificially iodized salt which is both cheap and easy to prepare.

7. Financing—Once the experimental studies were terminated, the Nutrition Division of the S.C.I.S.P. submitted for the approval of the Minister of Health in June, 1947, a project designed for two specific purposes: first, the artificial iodization of the salt from all the mines, and second, simultaneously with the first objective, to provide for the creation and the maintenance of the National Nutrition Institute for the study of the food and nutritional problems in Colombia.

The project for the financing of the proposed program consists essentially in the following phases: (1) the increase by 1 cent (Colombian) of the selling price of iodized salt over that of the common salt (this increase produces approximately Ps. 2,000,000 each year), (2) from this annual income, to pay the iodization expenses and to assign the total funds in excess of that cost for the creation and maintenance of the aforementioned Institute.

The original project of the Division of Nutrition was approved by the Minister of Hygiene and presented by him

to the Consejo de Ministros (meeting of national cabinet members) which entity also gave its approval. At the present time the proposal is under discussion by the National Congress, which body must pass it as a Law of the Republic. In the event that the proposal becomes law, the Division of Nutrition will have achieved two fundamental objectives: the prevention of simple goiter and the financing of a vast plan for the benefit of Colombian Nutrition. All this is being accomplished without burdening the budget of the Minister of Health nor that of the Servicio Cooperativo Interamericano de Salud Pública and at the cost of only 12 cents (Colombian) per annum to each inhabitant of the interior areas of Colombia. This accomplishment will be doubtless one of the most effective contributions of the Servicio Cooperativo Interamericano de Salud Pública in Colombia.

NOTE: The work and projects on simple goiter have had the approval and the unqualified support of the Directors of the S.C.I.S.P. in Colombia and of the Ministers of Hygiene throughout the entire period of the campaign. The Banco de la República—the entity in charge of the income proceeding from the exploitation of the salt mines throughout Colombia, has given every facility for the experiments on artificial iodization of salt on an industrial scale. In these studies and experiments, Dr. D. M. Hegsted of the Nutrition Division of the Schools of Medicine and Public Health of Harvard University—Asesor Técnico of Nutrition under contract to the Ministry of Health, Dr. Jacinto Caycedo—Medical Director of the Simple Goiter Commission in Colombia, and Dr. Alfonso Parra—Chemist of the Nutrition Laboratory—have given valuable assistance.

SUMMARY

1. Simple goiter is an ancient and serious problem of pathology in Colombia.
2. Surveys carried out on 140,000 school children, from 7 to 14 years of age inclusive, show an incidence of 56.5 per cent, including all sizes of goiter (+ to +++++). If there are excluded those cases of (+) value, the incidence is reduced to 35 per cent.
3. The history of simple goiter in Colombia, the process of its propagation to certain re-

gions of the country previously immune, and the marked difference of the incidence of the endemia between the school children of the interior (more than 50 per cent) and those of the maritime or coastal regions (less than 10 per cent) lead to the conclusion that the relative scarcity of iodine is the principal etiological factor of simple goiter, without excluding other factors such as anquilostomiasis (hookworm) and the quality of the drinking water.

4. In those regions of the Country where simple goiter is of long duration as an endemia (more than 100 years) there are observed cases, in children and in adults, with chronic defects in physical development (stature shorter than that of the average) and with evidences of mental retardment (mentally "dull" and cretins).

5. As a preventive measure against simple goiter in behalf of the entire population of Colombia there is proposed the artificial iodization of the salt from the land mines, in the proportion of 4 mg. of iodine per each 100 gm.

of salt. The average daily intake of salt per capita is 15 gm.

6. In order to finance the artificial iodization of the salt there is proposed an increase of one or two cents in the selling price per pound of salt. This increase will produce an annual fund of from 2 to 4 million pesos (approximately 1 to 2 million U. S. dollars).

7. From this annual income will be paid the iodization expenses and the remainder of the money will be destined to the creation and maintenance of the Instituto Nacional de Nutrición (National Nutrition Institute).

8. The project for the artificial iodization of salt and the creation and maintenance of the National Nutrition Institute is at the present time under discussion by the National Congress of Colombia and has already received the approval of the Special Commission of the Senate.

9. The approval and realization of this project will be one of the most efficacious contributions of the Servicio Cooperativo Interamericano de Salud Pública in the benefit of the Colombian people.

Budgets and Expenditures for Dentistry from Maternal and Child Health Funds*

A study of the dental programs of selected states, 1938-1946

JOHN T. FULTON, D.D.S.

Dental Services Adviser, U. S. Children's Bureau, Washington, D. C.

CONTINUOUS planning of programs is one of the essential elements of public administration. To plan effectively it is essential to review and appraise the nature and extent of past activities in a particular field. One of the continuing jobs of an administrator, therefore, is to "pull out the files" and to inform himself of the experience of others.

For the most part the development of dental programs in state health departments followed the passage of the Social Security Act in 1935 when grants in aid became available to the states to extend and improve health services to mothers and children. The Children's Bureau, in administering Title V, Part I, of the Social Security Act, makes grants-in-aid to states on the basis of an annual plan and budget which is submitted by each state for maternal and child health services. The Children's Bureau further requires that each state at the end of the fiscal year submit for audit a report of the expenditure of these funds.

An examination of these records for dental items helps us in appraising what has developed, and should establish

bench marks for the continued planning of public dental programs.

Such a study is now under way in the Children's Bureau, and this paper is in the nature of a preliminary report, covering the budgets and expenditures of eight selected states for a period of 9 fiscal years from 1938 through 1946. The material presented is limited to the items concerning dentistry which appeared in the budgets and audited expenditures of the states. Only those items were recorded that could be clearly identified as dental expenditures. Lump sum reporting of supplies, equipment, or educational materials may have included items for the dental programs, but it was not possible to extract such amounts. It should be pointed out also that the amounts reported to the Children's Bureau by the states cover only federal funds and the money used by the states for matching these funds. The reported amounts, therefore, do not necessarily represent the entire sum spent by the various states for dental services. It should be emphasized that findings in the study are preliminary and subject to review in the light of future analysis.

For purposes of administration, the Children's Bureau has established 8 regional offices. One state from each of these regional jurisdictions was selected for this preliminary report on the basis

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 2, 1947.

that the dental program of the state health department had been maintained continuously for the 9 years under study. No other criteria were applied in the selection of the states. Thus it cannot be assumed that these states constitute a representative example from a national or regional point of view. These findings are, however, descriptive of continuing programs in the states concerned.

While it is beyond the scope of this paper to discuss administrative or program content, it is interesting that 7 of the 8 states have always employed full-time dental directors. Four of the 7 have served for the entire 9 years. The 1 part-time director has also headed up his state's dental program since its inception. In 2 cases, the directorship has changed and in 1 of the states the dental program operated for 2 years without a dentist in charge.

It is interesting further that by 1942 all of these states had brought their dental personnel under state merit system classification plans.

Almost one and three-fourths million dollars were earmarked for dental programs by these state health departments, three-fourths of which were subsequently expended. The amounts budgeted range from \$68,000 to \$427,000 per state, with half the states budgeting in the neighborhood of \$150,000. The proportion of these budgets which was actually spent ranges from 55 to 93 per cent with half of the states well above 80 per cent and 1 other state closely approaching that figure.

The related weight of dental expenditures to the total sums spent for maternal and child health services varied from over 11 per cent in 1939 to 6.5 per cent in 1945, rising again to 10 per cent in 1946. In this computation the expenditures for this group of 8 states are combined for each of the study years. The percentage remains fairly constant for the first 3 years and then tends to decrease through 1945, but rises sharply

back to its former level in 1946. Trend for individual states was varied. In 1 of the states the trend was consistently downward through the entire 9 year period. In another of the states no trend was evident, while in the other 6 states there was a great amount of fluctuation during the 1940's. As the United States was engaged in war during 4 of these years, it is possible that these fluctuations were caused by man power shortages and scarcity of materials and supplies. At this point, however, such considerations are matters of conjecture. Detailed study of this trend was not possible with the present material and will be reserved for a later, more detailed analysis.

Concerning expenditures for dentistry in 1938 and 1946, the first and last years studied and also the proportion of the total maternal and child health expenditures used for dentistry in those years, our study shows that 6 of the 8 states increased the amount of their dental expenditures substantially. In the states where there was an increase in the amount of dental expenditures in 1946 as compared with 1938, the increase ranged from \$3,510 for state No. 2 to \$40,390 in state No. 1. In the case of state No. 7 the funds decreased by approximately \$5,000, and in state No. 8 the decrease amounted to nearly \$25,000.

A breakdown of the dental expenditures over the 9 year period according to object (salaries, travel, supplies, fees, training, and health education) shows that the bulk of the total dental expenditures was involved in salary items in all the states, with the exception of state No. 4, the overall proportion of the total for this item being 71 per cent. Items for travel demanded the next largest outlay (11.4), with fees (9.8), supplies (5.9), training (1.1), and health education (0.7 per cent).

The salary items cover a variety of personnel, in the main full-time em-

ployees. Part-time dentists on a salary basis were listed by 4 of the states, one of them as previously stated being a director of his state's dental program. A summary of the latest classification plans of the states illustrates the types of personnel which made up the bulk of these salary items. Although the titles vary somewhat in the different states, in general, the personnel fall into 6 classes:

- Director of Dental Health
- Senior Public Health Dentist
- Junior Public Health Dentist
- Senior Dental Hygienist
- Junior Dental Hygienist
- Clerks and Stenographers

Travel items were listed for all types of professional personnel and included out-of-state trips.

Supplies covered a wide range of equipment such as dental instruments, chairs, engines, cabinets, laboratory equipment and instruments, dental supplies, automobile and trailers, as well as general office materials.

As pointed out earlier, sometimes supplies were lumped together as one item in the reports of expenditures. It is possible, therefore, that the total given here may not represent the entire expenditures for such materials.

Fees included payments to practising dentists for correctional dentistry in clinics or private offices, and for inspection, diagnostic and preventive services.

It is interesting to note that state No. 4 reported a much higher total of expenditures for these fee items than for salaries. Expenditures for fees in this state made up 56 per cent of the

total dental expenditures. Fees represented 13 per cent and 9 per cent of total dental expenditures in 2 other states. In the remaining states the payment of fees to practising dentists for clinical service constituted a very small proportion of the dental expenditures in these state programs.

Training embraced both graduate education for full-time personnel and refresher courses for practising dentists. The former included stipends and tuition. The latter type of training included both lecturers and clinicians who visited local groups of dentists, and the sending of local dentists to dental schools for short refresher courses.

Health education items were expended for publications, printing of leaflets, exhibits, visual education materials and equipment, and for the organization and conduct of institutes for teachers and lay people. Here too, these materials may have been grouped in general supply item reports which would not show.

Material has been presented for 8 selected states on the budgets and expenditures of dental programs in state health departments. Recognizing the limitations created by the small number of the states included, and the incompleteness of some of the items, the study nevertheless illustrates a useful approach to the problem of studying growth and change in the size of dental programs. The procedure outlined also delineates the relative importance of different types of expenditures under dental programs.

Mass Control of Dental Caries Through the Use of Domestic Water Supplies Containing Fluorine

FREDERICK S. McKAY, D.D.S.
Colorado Springs, Colo.

BASED upon the generally prevailing rate of decay and tooth loss the forecast for the future is grim to the point of seriousness. A prediction published by an authoritative source as recently as June, 1947,¹ puts it as follows:

"It is estimated that . . . the 3,400,000 children born in 1946 . . . at 16 years of age will (each) require 7 fillings and 2 extractions and that 40 per cent of those reaching 40 years of age will require dentures."

Evidence collected during the past several years has established that the

continuous use of a domestic water supply containing even as low as approximately 1 p.p.m. of fluoride, during the period of tooth calcification, will bring about a mass reduction in the dental decay rate. As will be apparent later in this paper the conditions existing in fluorinated districts are in complete disrelation with the prediction quoted just above.

The evidence up to the present time has been derived almost wholly from examinations of children. There has been almost no information as to the dental

condition of adults who had acquired fluorosis of the teeth during childhood.

The data in the tables which follow were collected in the City of Colorado Springs, Colo., during the past three years, and are intended in part to supply this important information.

The observations summarized in Table 1 are not from a selected group of people but were made from persons as they presented themselves from day to day. All are natives of continuous residence with continuous use of the city water supply which has fairly consistently maintained a level of 2.6 p.p.m. of fluoride, since the first determinations were made several years ago.

The purpose of this paper is to show the actual condition that exists in this community after about 70 years of use of this water supply.

This is set forth in Table 1.

In addition to showing the average decay experience rate (untreated and filled teeth) in the different age groups, the table shows that this rate for the entire group is 2.98 per person. It will be noted also that slightly more than one-third (35 per cent) of these persons had experienced no decay whatever. The average age of the group is about 25 years. The age groups 10-14 and 15-19 show the remarkably low decay experience rates of 1.09 and 1.51 respectively, the decayed areas being practically limited to the fissures and pits in the molar teeth. The low incidence of caries experience in fluorosed upper anterior teeth cited by Dean² is confirmed by the present study, in which it was found that of the 1,192 teeth showing caries experience only 45 were in the incisor and cuspid group.

From the above it is apparent that decay of the proximal surfaces of fluorosed incisors and cuspids is almost negligible. The "standardized rate" of tooth loss as it appears in Table 1, has been accepted as a measure of the prevailing tooth loss from all causes. Table

1 shows a slowly increasing average decay experience rate as the ages advance, for which no explanation is suggested, but it is important to note that at the highest average rate shown (the 40-44 year group) the rate is considerably less than the *tooth loss* rate in the "standardized rate" table. The significance of these rates of decay experience and tooth loss can be best comprehended by comparison with a non-fluoride community such as the City of Madison, Wis.* This comparison is shown in Table 2 which was compiled by Dr. John G. Frisch of Madison.

The observations summarized in Table 3 were made in Colorado Springs and Montrose, Colo.,³ the persons examined having acquired fluorosis of the teeth in other widely scattered communities and districts through the use of domestic waters containing fluoride. These districts were generally in the middle and southwestern states and in other parts of Colorado.

Tables 1 and 3 bear a close similarity. Perhaps the most important comment pertaining to Table 3 is that the inhibitory effect of fluorine, once acquired, is permanent and is not diminished by later migrations. It is not necessary that the use of fluorinated water be continued. It is indicated also that the average rates of decay experience and tooth loss shown in Colorado Springs are by no means peculiar to that city alone. Examinations made in other communities using fluorinated water supplies, in various parts of the country, have shown that the average decay rate remains consistently at about 3 and that about one-third of the native persons are caries-free.⁴

It seems, therefore, that a pattern has been established which indicates what may be expected in any community that uses a fluorinated water supply. Bearing

* Madison is one of the cities that have recently undertaken a project for fluorination of its water supply.

on the relation between the degree of fluorosis of the teeth and the caries experience rate, a significant observation made on the Colorado Springs group was that in 137 of the first 300 persons examined the degree of fluorosis was classified as "mild." Their average caries experience rate was 2.46 and 55 (40 per cent) of this group were caries-free.

It has not been maintained that any benefit will accrue to teeth formed prior to the use of fluorinated water, and yet it cannot be said that this will not be the case. Reliable evidence bearing upon this point would be difficult to obtain, but there is a feeling that such teeth may experience some benefit.

Primarily this is a long-range influence directed toward the reduction of tooth decay in children and at the same time endowing the teeth with a resistance against decay that extends, as the tables show, well into adult life.

The chief research project in dentistry has been and still is to determine the

cause of decay and to devise means for its elimination. No caries reduction program encountered thus far has succeeded in delivering any considerable segment of a mass population into adult life with an average caries experience rate of about 3 and a complete absence of decay in approximately one-third of a native population, as has the use of a domestic water supply in which fluorine is a natural constituent. Some twenty-five communities in this country have accepted the evidence as sufficiently conclusive to warrant the addition of fluoride in a proper proportion to their domestic water supplies as a means of reducing the decay rate. If in the future some method of further reducing the decay rate should be available, it need not necessarily be in conflict with the action exerted by fluorine.

Sixth Annual Meeting United States-Mexico Border Public Health Association

The Sixth Annual Meeting of the United States-Mexico Border Public Health Association was held in Laredo, Tex., and Nuevo Laredo, Mexico, March 20-22. Nearly 300 persons were in attendance with almost as many from the South of the Border as from the North.

Sessions were held on international coöperation in health, on Border sanitation, on tuberculosis and its control, with special reference to BCG, on meningitis and other communicable diseases, and on the problems confronting the mother and child. Excellent exhibits were shown from the Section on Public Health Education of the Ministry of Health and Welfare of Mexico. Coöperating agencies beside the Ministry of Health were the U. S. Public Health Service, the Ministry of Hydraulics in Mexico, the Ministry of Agriculture in Mexico, the Institute of

Inter-American Affairs, the U. S. Children's Bureau, the International Boundary and Water Commission, the Rockefeller Foundation, the University of Vera Cruz, the Texas Tuberculosis Association, the Crippled Children's Foundation, and the Pan American Sanitary Bureau.

It was decided to hold the meeting in 1949 at Nogales, Ariz., and Nogales Sonora, Mexico.

The new officers for the Border Public Health Association were elected as follows.

President: Dr. Victor Ocampo Alonzo, Hermosillo, Sonora

President-Elect: Dr. George W. Cox, Austin, Tex.

Vice-Presidents: Dr. Jose Angulo Araico, Mexicali, Baja, Calif.; Dr. J. P. Ward, Phoenix, Ariz.

Secretary: Dr. M. F. Haralson, El Paso, Tex.

Pro-Secretary: Dr. Gustavo A. Rovirosa, El Paso, Tex.

Role of the State Health Department in the School Dental Program*

J. M. WISAN, D.D.S., M.S.P.H., F.A.P.H.A.

Dental Director, State Department of Health, Trenton, N. J.†

STATE departments of health are accepting six responsibilities¹ in the conduct of school dental programs. Briefly, these responsibilities are:

1. Studying and planning for the solution of dental health problems
2. Coördinating and advising local agencies
3. Subsidizing local programs
4. Establishing standards for dental programs
5. Disseminating authentic dental health information
6. Coöperating with other state agencies

While the listed functions indicate that state departments of health are exhibiting characteristics of leadership, the actual performance in conducting school dental programs does and should rest with local personnel.² The state department of health within this concept functions as an interagency. How indispensable local participation is for meeting dental health needs will be discussed under each of the listed functions.

1. *Studying and planning for the solution of dental health problems*—A local board of education or a local board of health conducts surveys to determine the prevalence of dental defects among school children. It is desirable that local personnel be aware of the dental needs of their children. However, the value of the findings will be enhanced if local

authorities are able to compare conditions found in their community with conditions found in other situations.³ By utilizing comparable data obtained under similar or nearly similar conditions, the effectiveness of program technics can be evaluated. Not only can results of programs be reliably measured, but also costs can be accurately estimated by uniform reports.⁴

State departments of health should designate inspection charts and recommend techniques for dental surveys, so that uniform procedures may be utilized throughout the state. After dental conditions found in local areas are carefully analyzed, the state department will be able to make recommendations for dental programs, not by theoretical armchair thinking but by accurate estimates.

A number of state departments of health are conducting demonstration and research projects. Among the phases being studied are the fluorination of communal water supplies, the topical application of 2 per cent sodium fluoride, incremental dental care procedures for children, dental care time estimates, and evaluation of health education devices.

2. *Coördinating and advising local agencies*—When local dental programs are supported by health, welfare, and educational agencies, maximum results may be expected; but competent leadership is required to develop such coördination. When requested to do so, a state dental administrator usually finds it less difficult to accomplish rapport of local personnel than does a home-town

* Presented before a Joint Session of the American School Health Association and the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

† Present address: Director, Division of Dental Health Education, American Dental Association, Chicago, Ill.

official. Moreover, because of his objective viewpoint, a state administrator is better able to recommend desirable changes or improvements.

In New Jersey the dental health division of the State Department of Health has found it profitable to help organize dental health committees representing local schools, health departments, nurses, dental hygienists, parents and teachers, and other groups interested in child health. In some instances, these dental committees operate solely to promote the dental program; in other places, they operate as subcommittees of health councils or committees.⁵

3. *Subsidizing local programs*—Many rural and suburban communities have neither facilities nor funds to maintain effective dental programs. Particularly is this true of dental treatment programs. State departments, being the agents for distributing federal and state health funds, are able to subsidize dental care programs in the sparsely populated areas.

However, contributing money does not warrant the establishment of authoritarian policies by a state department. Such details as designating children entitled to treatment, scheduling treatment hours, appointing dentists, might well be the responsibilities of local agencies. Also, local personnel might profitably be permitted to decide whether clinics, private offices, or mobile clinics are to be utilized. Moreover, the local dental society should be invited to recommend policies for the program.

Subsidies provided by state departments of health may take several forms. The state may pay all or part of the salaries of dentists; dental equipment and supplies may be provided. In rural areas, many state departments are providing trailers, automobile clinics, station wagons, or portable dental equipment.

Some communities will find it necessary to have the state dental adminis-

trator help in supervising dentists participating in the local dental program. When requested, and only when requested, such supervision should be provided because competent professional supervision of a dental care program will improve standards of treatment.

4. *Establishing standards for dental programs*—Under the heading "Subsidizing Local Programs," the need of assigning responsibilities to local agencies was stressed. However, local school administrators should seek the advice of state dental directors before instituting dental programs. Most state dental directors are following the recommendations of the U. S. Public Health Service, the Children's Bureau, the Council on Dental Health of the American Dental Association, the American Association of Public Health Dentists, and the National Committee on School Health Policies. The following are a few of the basic policies recommended:

- a. Simplified and uniform examination procedures should be used.⁶
- b. Record forms approved by the American Association of Public Health Dentists should be utilized.⁷
- c. Dental treatment programs should begin with younger children with subsequent incremental care provided.⁸
- d. Topical applications of 2 per cent sodium fluoride should be provided four times a year for children.⁹
- e. All necessary fillings and extractions should be provided for children included in the community treatment programs.¹⁰
- f. Authentic dental health information should be used as content material in the health education programs.
- g. Desirable motivating devices should be used in the health education programs.

If the state department of health is to fulfil this role of establishing standards for dental programs, recommendations should be presented in printed or mimeographed leaflets.¹¹ To obtain uniform data, the state department should print forms and charts in large numbers so that they can be either distributed free to local agencies or sold at cost.

5. *Disseminating authentic dental health information*—Physical education personnel and classroom teachers require guidance in selecting dental health education material. The dental bureau of the state department of health should be prepared to offer this guidance by means of field visits or by printed or mimeographed material. Informative leaflets, source units, and manuals, have been printed by state departments of health. Also, nearly all state departments purchase material published by the American Dental Association for distribution among local personnel.

State departments of health should organize state and local committees to prepare dental health education material.^{12, 13} This collaboration is highly recommended because it results in broader concepts and avoids the disadvantages of specialized thinking. State departments of education, state departments of health, state dental societies, state departments of welfare, state agricultural colleges, state teachers colleges, dental schools, state nursing organizations, state organizations for physical education, may collaborate in preparing authentic dental health education material.

The distribution of visual aids, such as movies, slides, posters, models, and charts, has been found worth while, particularly if directions for their proper use accompany the material. Health educators have informed us that visual aids as well as printed materials are to be used only as tools; that the chief objective of health education is not mere information but desirable changes of dental health practices.

6. *Coöperating with other state agencies*—Equally as important as coördination of local agencies in the conduct of local dental programs is the collaboration of all state health, welfare, and educational agencies for dental objectives. In most states we find a number of state agencies, both official and non-

official, involved in local school health programs. Since their policies are usually set by their state administrators or state officers, it is imperative that the state dental bureau work closely with these state organizations. In the case of welfare agencies and such nonofficial groups as a state congress of parents and teachers, procedures in the local areas are directed by the state leaders. After the state dental director has cleared with the state office, it is much easier to function with the local representatives of these state groups.

SUMMARY

It has been shown that the state department of health may operate as an interagency encouraging effective dental health programs in local communities. If it accepts this responsibility by employing democratic techniques, maximum results will be obtained by providing expert guidance on the state level and encouraging active participation in the local communities.

Health Problems Resulting from Newer Technological Developments*

R. EMMET KELLY, M.D.

Medical Director, Monsanto Chemical Company, St. Louis, Mo.

THE health problems associated with the newer technology have been most prominent ever since the news of the atom bomb was released. Other wartime and post-war developments have contributed to our peacetime health hazards. Before discussing some of these, I wish to emphasize two related facts.

The first is that not all of the old problems of industrial medicine have been solved. On the contrary, new ones have arisen in the use of materials that well qualified observers had previously assumed were well controlled. For example, an innocuous substance such as talc, or at any rate one formerly believed to be innocuous, is now being investigated as a cause of pulmonary disability. Likewise, workers who have been employed in atmospheres well under the maximum allowable concentration of silica appear in some cases to be developing silicosis. Thus, as there is an advancing front of medical problems arising from the contact with newer products, a struggle in the rear areas with the old compounds continues.

The second point is that much of the newer information is still not generally available because of security restrictions. This includes important medical and industrial observations on microwaves, biological warfare, and radioactive materials.

The advance in industry has developed along several pathways. I will discuss only the five most prominent: radioactive materials, newer chemicals—both in substance and application—newer metals, microwaves, and ultrasonic waves.

Radioactive materials have been rightly considered by the lay and the professional public to be the key to the technology of the future. We are limiting ourselves in this discussion to health problems, and so the many actual and potential benefits which radioactive isotopes afford to medicine and industry will not be dwelt upon.

To evaluate the health hazards associated with this field, let us see what the exposure is, how widespread it will be, and what ill effects have been reported to date.

Radioactive materials emit a variety of radiations but they all exert effects that are roughly similar. The deleterious effect on human beings is produced by setting up destructive ionizing reactions in the tissue. The response varies with the type and amount of exposure. Damage to the germinal cells, the bone marrow, and the lymphatic tissue, and the occurrence of malignant changes comprise the conditions to be expected and guarded against. Experimentally, these results are easily demonstrated. Exposure to sufficient gamma radiation or the introduction of an alpha emitter in a sufficient quantity (and remember even a fantastically small amount may be a sufficient quantity) has produced sterility.

* Presented before the Industrial Hygiene Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

Leukemia has resulted from bombardment from a neutron source, and a variety of malignancies have been produced by exposure to fission products. The work of Brues, Lisco, and Finkel,¹ as reported at the 1946 Gibson Island Research Conference on Cancer, is interesting in this connection. Using strontium (Sr^{90}), bone tumors and lymphoma were produced; ytterbium 91 (Y^{91}) caused intestinal lesions with obstruction, and plutonium (Pu^{239}) caused splenic atrophy and gross liver damage. After the subcutaneous injection of one gamma of Pu^{239} localized fibrosarcomas appeared within one year, and localized ulcerative lesions and spontaneous amputations occurred.

Obviously, radioactive substances are inherently hazardous, but can they be handled and used safely? The answer is uncompromisingly yes. Before developing this statement, let us consider how widespread is their use.

On August 2, 1946, the first shipment of radioactive isotopes produced in the chain reacting pile at the Clinton Laboratories at Oak Ridge, Tenn., was made to the Barnard Free Skin and Cancer Hospital in St. Louis. During the following year over 1,000 shipments were made throughout the continental United States and the Territory of Hawaii. These shipments approximated 1,500,000 miles, and were sent to about 150 scientific and research institutions. These isotopes are being used in fundamental research, in medical research and treatment, in cancer study and treatment, in biological research, and in industrial research. Radioactive isotopes are used in oil well logging, in metallurgy, in aircraft engine development, and in structural analysis of heavy objects, such as castings and girders. In agriculture, tracer elements are used to study soil chemistry, plant hormones, photosynthesis, and the entomological aspect of farming. To date no ill effects, apart from

accidental exposure, have been observed as a result of the industrial use of radioactive isotopes. This for this is simple. It gives grounds for complacency but rather an indication of what control measures must be exercised in the future. Effects from chronic radiation have not occurred because careful attention to details of protection has made the production, transportation, and use of these isotopes safe. For example, at Clinton Laboratories the budget of the health physics group amounts to more than \$250,000 annually. Their job is monitoring and supervising the radioactive material from the time it enters the pile until final disposal occurs. Shipping containers vary from less than a pound to a ton, averaging 150 lbs. In one case a 23 gm. unit (approximately the weight of a half dollar) containing radioactive cobalt (Co^{60}) was shipped in a container weighing 1,600 lbs. Other meticulous details are carried out, such as checking the radiation of truck wheels before trucks leave the laboratory to avoid radiation damage to the driver in the event of changing a tire.

It has been shown that radioactive materials can be manufactured, transported, and used safely. Maximum allowable concentrations have been established for all types of radiation. The methods of detection and the means of protection from radiation are so adequate and well tested that only the careless, the uninformed, or the foolhardy should suffer exposure. This is borne out by the record of the Manhattan District plants and the Atomic Energy Commission installations, as well as by the absence of injury to the 70,000 people taking part in the Bikini experiments.

For the future I see three health problems in this field. The first is accidents and their prevention. When working with fissionable products there can be spills, breaks, and other unfore-

ces that will produce
cient to cause serious in-
Health. This has occurred and,
will continue, but the inci-
has been and should be very
The second is unfamiliarity or in-
cient knowledge of how to handle
ese materials. As the number of in-
stitutions using these products swells
from 150 to the thousands, there will
be workers who will not abide by the
tolerances and safety rules laid down.
Then too, more detail work will be per-
formed by individuals lacking the
physicist's viewpoint.

The following example is typical of
what might be expected: In a southern
hospital a medical technician was carry-
ing out analytical procedures with a
radioactive substance (which paren-
thetically was not received from the
Atomic Energy Commission) in a
manner which was subjecting her to
total radiation of many times tolerance.
Her superior had failed to assure him-
self that everyone in the laboratory
knew and practised the essentials of
protection. As the actual work stems
down farther and farther from the in-
dividual to whom the material is sent,
this hazard grows. One need only
couple the deformities and skin cancers
of our early radiologists with the fact
that present radiologists have a leukemia
rate eight times that of males of a
comparable age, to understand that
progress in protection for scientific
workers comes slowly. We then receive
a view of what may be in store for
workers in the future unless adequate
supervision is maintained.

The third problem is that of chronic
low level exposure. Most investigators
and workers will be using negligible
amounts of radioactivity in tracer ex-
periments, and only simple precautions
will be needed. However, when we
calculate the sum total of all the radio-
active isotopes used over the entire
country, and as some (carbon 14 for

example) have a half life of over 5,000
years, the serious character of the dis-
posal problem becomes evident. Simply
diluting the material and letting it pass
into our streams and rivers will not
suffice. The radiation would continue
and be built up with successive dis-
posals. This problem is being investi-
gated by everyone concerned, but the
final answer has not been found.

The industrial chemical field is broad-
ening too rapidly and too extensively
for me to do more than select one com-
pany as an example of the methods of
handling the problems associated with
new products. In 1946 this company
developed over 50 new products, and it
is expected that in 1947 at least as
many more will be produced.

The problem for a manufacturing
concern is to make certain that no
product is used in a manner in which
systemic toxicity or skin irritation
might result to its workers or consumers.
It is impossible to obtain toxicological
information on 50 or so compounds in
a year, but those compounds that have
an application where ingestion or skin
contact is a factor must be examined.

For example, every new textile chem-
ical, such as the melamine resins, is
subjected to a laboratory study for
systemic and skin reaction, culminating
in patch testing on 200 human subjects.
With plastics and plasticizers, animal
experimentation, involving in some
cases two year feeding tests, must be
made before they can be marketed.
Some substances, such as polystyrene
and some plasticizers, are so innocuous
that they can be used in any applica-
tion, while the use of others must be
more limited.

Certain new chemicals used as bi-
ocides, such as hexaethyl tetraphosphate
or sodium fluoracetate, possess a high
level of toxicity, and investigations must
be carried out on their pharmacological
activity to allow them to be used safely.

Simply stated, the problem for the

megacycles per second or higher. Their wave length varies from 30 cm. to 1 cm. These radiations had been generated prior to 1939 but their wartime use in radar vastly stimulated their use and development. These high frequency radiations are the basis of the electronic field and have wide industrial application. It is important that their effect on the workers be determined.

Microwaves have optical properties. They can be focused and may be selectively absorbed by various media such as water, oxygen, and, presumably, tissue. Up to now the only biological effect noted has been the production of heat similar to medical diathermy. There has been no ill effect discovered either clinically in workers or experimentally in animals.³⁻⁵ Studies have been carried out on animals exposed to continuous radiations 3 hours a day for 53 days. There were no gross or microscopic tissue changes, and no effects noted on growth or reproduction.

One group of 45 men who were exposed while operating radar for 2 months to 9 years, and another group of 124 men who were exposed for 2 months to 3 years, were examined. There were no abnormal clinical or laboratory findings and no effect on the blood forming or reproductive systems was found. It appears therefore to be fairly well established that the present high frequency radiations exert no ill effect on exposed workers. Future scientific developments in this field, however, must be accompanied by biological experimentation because we cannot assume that wave lengths of new frequencies will not cause damage.

Ultrasonic waves, sometimes called supersonic waves, are elastic vibrations in any solid, liquid, or gaseous medium of a frequency above the range of audible sound (16,000 cycles per second). Their application has varied from submarine detection to the soundless dog whistle, but while at present

it is limited, much future development may occur. Ultrasonic apparatus has been devised which transmits silent sound vibrations powerful enough to ignite paper, and has been considered for such applications as eliminating bacteria and molds, drying inks, and breaking up suspensions of solid particles.

Ultrasonic waves follow the physical laws of audible sound with the addition of some phenomena due to their high frequency. Biologically, they exert a very different effect. Since 1928 ultrasound has been shown to have destructive capabilities for biological tissue. The changes induced vary from simple heat generation to cell rupture. Sudden explosive liberation of dissolved gases in the target tissue has occurred. In one experiment, 37 animals were subjected for 5 to 15 minutes to focused ultrasound produced by expansion and contraction of a quartz crystal.⁶ Reversible and irreversible nerve tissue damage was produced, causing cortical blindness, paralysis, ataxia, or death.

In this experiment the sound traveled only a few millimeters to the animal but it is possible that future industrial exposure to ultrasonic waves may be dangerous. The indications are that the danger limits will turn out to be very high and probably will be encountered only under special conditions. There have been no studies on this phase of the problem in the literature as yet but obviously they are indicated.

The problems already discussed constitute an important but incomplete segment of our newer peacetime technology. I have not included the problems of the new developments in aviation, in industrial biology, in acceleration, or temperature changes. There has been no mention made of the new weapons of destruction—the radioactive cloud, the atom bomb and biological warfare, or the results associated with them. An attempt has been made to omit the purely theoretical advances

Proposed Report on the Educational Qualifications of Community Health Educators^{*†}

I. GENERAL SCOPE OF HEALTH EDUCATION

The health educator helps individuals and groups to recognize, understand, and share responsibility in solving personal, family, occupational, and community health problems. From facts secured with the aid of technical specialists, he interprets health needs, desirable health behavior, and the services of professional health agencies. He develops situations in which actual learning takes place on the basis of factual data provided by technical experts in medicine, dentistry, engineering, nursing, nutrition, and other sciences.

A successful total program of health education in a community requires more than publicity alone. It requires the development of satisfactory learning experiences within organized groups in school and community. It includes the training of other personnel, in the fields of health and of education, to make effective use of the educational opportunities presented by their contacts with individuals and groups. The health educator supplements, in an organized and continuous way, the work of other

educators and public health workers, but he replaces none of them.

The first program of study in health education ever offered in a school of public health was established in 1921. Since that time the emphasis upon health education and the demand for properly trained health educators has constantly increased. Health education is now an important field of service in the modern public health program, with recognized techniques and procedures.

The Committee on Planning in Health Education of the Public Health Education Section of this Association, in an unpublished report, estimates that about 460 health educators are now employed by health agencies, about 300 of whom have completed graduate courses in recognized schools of public health. A survey by the committee at the beginning of 1947 indicated that these health educators were distributed as follows:

| | |
|------------------------------------|-----|
| Federal health organizations | 14 |
| State health departments | 160 |
| City and county health departments | 126 |
| Voluntary health agencies | 160 |
| Total | 460 |

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council, in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

† This proposed report is a revision of the Report on the Educational Qualifications of Health Educators approved by the Governing Council on October 13, 1943 and is intended to supersede the earlier report.

No data are available concerning the number of health educators employed by schools and colleges.

The committee just mentioned has estimated the need for health educators on the basis of present population groups, health departments, school systems, and voluntary health agencies, to be as follows:

| | |
|---|----------------|
| Local health departments | 1,948 |
| State health departments | 219 |
| Federal health agencies | 40 |
| Voluntary health agencies (all levels) | 2,331 |
| Local school systems (supervisors) | 1,311 to 2,300 |
| State school systems | 48 |
| Federal office of education | 6 |
| Teacher training institutions | 310 |
| | <hr/> |
| | 6,213 |

This estimate omits specialists like writers, editors, audio-visual specialists, research analysts, photographers, and librarians, of which health departments were estimated to need 335. It omits also the health teachers, employed or needed in the 29,000 public high schools and other secondary schools and the few hundred in colleges other than teacher training institutions.

These figures as well as the present acute shortage of adequately trained health educators give promise of employment and useful service for the young man or young woman entering the field. Increasing recognition is being given to the importance of the total, unified, community-wide program. Promotional progress may thus be anticipated by the beginning health educator both through the expansion of his program and through transfer to the service of larger population groups, as his ability is demonstrated.

The health educator in the health department works under the administrative leadership and direction of the health officer. The health educator working in the school system as a teacher, coördinator, supervisor, or consultant, is a member of the staff of the school and will, of course, meet whatever professional educational standards are set by the school for the type of work involved. The health educator in a voluntary health agency is employed as a staff member or as executive secretary. A health educator serving the total community may be jointly em-

ployed by health department, school system, and voluntary health agency, or by any combination of them. Joint planning is needed in any community-wide program.

The educational qualifications of the health educator, whether employed by a governmental or by a voluntary agency, should meet generally accepted standards. This report proposes *desirable areas of competence for the community health educator*, based upon the functions which he is expected to perform. The recommendations are made for the guidance both of officials responsible for the appointment of health educators and of individuals looking forward to careers in health education.

The professional standing of persons now performing creditable service as health educators has been established. Successful experience and demonstrated ability should be recognized at the present time as evidence of professional qualifications.

Educational qualifications for health educators working entirely within a school system although needed are not proposed in this report, as the preparation of such qualifications is not a function of this Association. Schools have their own planned and organized program of health education which should be a part of the total community program. Schools are broadening their concepts of their health education responsibilities to include a consideration of home and community, because they find that children cannot practise what they learn at school unless adult customs in the home permit it. At the same time health departments are recognizing that community programs of health education in which schools do not participate have lost much of their potential influence.

Other forces are moving us toward unified community programs. Other groups, like agricultural extension workers, are beginning to incorporate health education in their program.

Voluntary health agencies are finding that sporadic educational programs promoting a single goal may prove to be ill timed, competing, confusing, and ineffective. They are turning to community planning and cooperation.

The recognition that all health educators should concern themselves with the total community program has brought with it a realization of the breadth of training that all health educators need. Health authorities have realized that this public health worker is an educator by profession, that he works with schools and needs training in general education and school health education as well as in public health education.

School authorities have realized that health educators in school systems need instruction in public health and the work of public health agencies as well as in hygiene and the public school procedure. In suggesting the training of the community health educator the committee has in mind that in the absence of a school health educator, he will work with school administrators, supervisors, teachers, and curriculum committees, but that he will not ordinarily supervise classroom teaching. State laws, school authorities, and professional groups in education have set requirements and credentials for teachers and supervisors at various levels. Such standards are not a responsibility of this Association. The committee believes, however, that the health educator who meets such standards in general education and also the qualifications listed below, will have an excellent professional background for school health education.

II. THE FUNCTIONS TO BE CARRIED OUT IN THE TOTAL PROGRAM OF COMMUNITY HEALTH EDUCATION

The following functions are believed to be essential for carrying out complete community-wide programs in health

education. They are not the functions of any one health educator and it is not expected that any one health educator will have special skills in all the knowledge areas involved. Health educators in various positions, however, will be expected to undertake some or all of the following functions or activities which involve the formulation of plans and methods, the application of specific techniques and skills, the supervision of the work of others, and the maintenance of group relations.

The functions of health educators in community-wide programs of health education are:

In accordance with the administrative policy of the health department or other employing agency:

1. To assist in planning and organizing a program of health education of suitable scope and activities to meet adequately the needs of the community, state, or area to be served. This includes, at the outset and continuously thereafter, a study or survey of the needs and resources with the aid of technical experts and the determination of health problems by lay and professional groups.
2. To assist the area to organize for health education.
3. To assist in establishing and maintaining close, cooperative, working relationships between all agencies (official and nonofficial) which may contribute to health education.
4. To aid in stimulating, organizing, and guiding in-service training programs in the field of health, for employed personnel, in accordance with the policy of the agency or institution involved; including:
 - a. Health agency personnel
 - b. School personnel
 - c. Personnel of other agencies
5. To aid, in accordance with the policy of the institution concerned, in planning the health education aspects of pre-service training programs for professional personnel, including: (a) public health personnel, (b) school personnel, and (c) others.
6. To provide consultation and guidance to various individuals and groups (such as Parent-Teacher Associations, service clubs, and others) in developing and improving

the health education aspects of their programs.

7. To assist in promoting, organizing, and guiding study groups in the field of health for adult and group work agencies, such as divisions of adult education or young people's clubs.
8. To contribute to the improvement of the quality of the health education of pupils or students in accordance with the standards and policies of the school system or institution (in the absence of or in coöperation with a school health educator).
 - a. Through aid in planning school health programs and curricula of health instruction
 - b. Through conferences with teachers, supervisors, and school administrators
 - c. Through such other educationally sound activities as the school may desire
9. To assist in stimulating and establishing adequate public health and school health library facilities.
10. To assist in organizing and operating an informational service to provide answers to inquiries; and in answer to requests, to suggest source materials and source references.
11. To be responsible for the preparation, selection, assembly, and distribution of health education materials, using the services of special technicians and health experts whenever possible.
Such materials include:
 - a. Reports and other printed materials
 - b. Visual aids, such as motion pictures, film strips, photographs, graphic materials, exhibits, and posters
 - c. News releases and radio scripts
12. To organize and assist in conducting a speakers' bureau, conferences and meetings.
13. To assist in planning and, in accordance with the policy of the agency, in preparing the health education budget.
14. To encourage, and assist in the development of efficient records and reports of all health education activities in order to facilitate the quantitative analysis, evaluation, and interpretation of the health education program.
15. To assist in the establishment and employment of methods for continual appraisal, in order to evaluate the effectiveness of all phases of the total health education program.

A job analysis of existing positions reveals wide variations in their scope. In general the health educator employed

by a health agency is (1) a director of health education, or (2) a staff member with the title of health educator. Other specialists such as editors, audio-visual specialists, research analysts, photographers, and librarians are commonly employed in the larger agencies.

III. EDUCATIONAL BACKGROUND

The procedure used in determining the desirable educational qualifications here listed, was to analyze each of the above functions in terms of needed professional qualifications in basic sciences, social sciences, and public health, and to group these qualifications in suitable areas.

Certain facts should be borne in mind in approaching this discussion. Not all positions in health education, as indicated above, are of the same scope. The health officer or other appointing authority may not deem it necessary to require all the qualifications listed below for every position. *They are the qualifications believed desirable for the director of a large and complete program.* Nevertheless it is believed that the continuing improvement in the training of health educators will provide more and more workers who have this training, and that such a person will eventually prove most useful.

Experts in various techniques who are not health educators are commonly needed to assist in editorial work and in the development of films, exhibits, and other graphic materials. The health educator concerned with the production of such material will know the nature, limitations, and possibilities of the processes involved. He will know how to work effectively with printers, motion picture producers, and other specialists. This report does not consider the qualifications of these technical experts.

It is clear that the health educator will be helped by a broad cultural background and by a knowledge of (a) the structure, functions, and care of the

body, elements of the more common pathologic processes, and elements of epidemiology and public health procedures; (b) motivation and behavior in human life; (c) society as it is constituted, social forces and their control; (d) forces which affect living-environment and economics; (e) the scientific method in approaching the process of living, distinguishing science from pseudo-science; and (f) the processes of education—why we learn and how we learn.

There is also need for knowledge and skills which are more specifically professional in nature. The division between essentially basic preparation and strictly professional training cannot be readily drawn. It is not the purpose of this committee to indicate here a specific training program in terms of institutions to be attended, degree secured, years of study, or specific courses taken.

Some health educators have begun training for this field immediately upon reaching the university level. More will do so in the future with the increasing number of schools offering an undergraduate health education major.

At the same time it is recognized that several of the professional fields in the health and social sciences, including education, contain many of the elements of training which are desirable for the health educator. Many successful health educators have acquired their training through supplementing the training in one of these professional fields by study in those previously omitted areas of knowledge which are required for health education. It is not feasible to discuss here the entrance into health education from various professional fields. We shall not attempt to define optimal training. We shall attempt to state the essential qualifications.

Present requirements in the training of health educators should be sufficiently flexible to be adapted to the scope of

work required from the individual concerned. There follows a statement of desirable backgrounds and competencies for the health educator, organized under 7 major areas and based upon the duties to be performed in a complete program of health education. The major purpose of this statement is to help those who may wish guidance in preparing for a career in health education. It does not represent recommended minimum criteria for a graduate degree in public health or health education.

1. In the field of *Basic Cultural Education* involving the development of appreciations and skills in the use of the English language, it is assumed that all health educators will have had instruction in English literature, and English composition, and that most health educators will have had some background in general psychology, United States history, and world history.
2. In the *Basic Sciences* it is assumed that all students will have some knowledge of general chemistry, bacteriology, and the structure and function of the human body. Many students will also have had some training in organic chemistry, physics, and biology.
3. Training in *Education and Educational Psychology* is important to provide a knowledge of and functional experience with the learning process, principles and practices of education, methods and possibilities of adult education, the nature of the school health program, educational supervision and administration, and in-service training. It is assumed that all students will have some background in educational psychology and the principles, theory and social aspects of education, as well as professional training and field work in school health education and in public health education, including community organization. Many students will also have had an opportunity to study child growth and development, the elementary and secondary curriculum, and school administration. Some health educators will have had much more extensive study in this field.
4. In the *Social Sciences*, where we are concerned with the racial, social, and cultural characteristics of people and their mores, and the significance of the economic status of population groups, it is assumed that all health educators will have some background in general sociology and that most of them

have some knowledge of political economy and cultural anthropology. If the Health Educator should have come from the social work field, he may have given special attention to comparative religion, social dynamics, and special problems of race relations and of publicity.

5. No health educator can be expected adequately to understand and interpret scientific health facts or the work and program of technical experts and health agencies without sufficient *public health* training to give him a knowledge of basic principles in the organization and administration of public health, personal hygiene (including mental hygiene and nutrition), environmental sanitation, methods of communicable disease control (including the nature of causative organisms and methods of transmission), public health statistics and the principles of statistical reliability, and the nature (not necessarily the skills or technics) of public health laboratory procedures.
6. In *Public Administration*, where we are concerned with governmental and community organization, the nature and functions of community agencies, and principles of planning, all health educators may be expected to have some background in social work agencies and most of them will have had some instruction in the field of government.
7. There are many needed *Special Skills in Health Education*. These include public speaking; the use of methods and materials; evaluation of sources of material and information; the writing of informative and friendly letters; the compilation of bibliographies; filing and clipping methods; the writing and editing of material for publication; the use of the printing and duplicating processes; effective distribution of educational material; the nature, preparation, and use of visual aids; possibilities of community participation in the development of educational material; press relations and technics; the organization and conducting of meetings; technics for the interview and consultative conference; the discovery of leaders and the way to work with them; and the use of group work methods. It is expected that instruction in public health education and school health education supplemented by field work and practical experience added to the background of general education will have provided these special skills at least in some degree.

IV. GRADUATE INSTRUCTION

The courses in public health are

usually covered at the graduate level. This training furnishes the professional, factual background of the health educator, who will profit by having such instruction presented by specialists, by studying in some of these areas with other public health workers like those with whom he will be professionally associated, and by having his instruction in these rapidly developing sciences just before beginning his professional career.

If the Bachelor's degree is not taken in a teacher training institution, much of the work in education will usually need to be taken after the Bachelor's degree, but it is desirable that most of the work in general education be taken prior to the graduate training in public health and health education. The more highly specialized professional public health courses should not be pushed down into the undergraduate level.

Some colleges and universities are offering a four year undergraduate major leading to a Bachelor's degree in health education. Usually the program is organized through the school of education, and the emphasis is upon *school health education*. This training usually prepares one to become a member of a school staff in the capacity of health teacher or coördinator. Well planned programs of this type serve as a means of supplying more trained people in school health education, and as a valuable reservoir from which to select well qualified students for the graduate training in *community health education*.

At least three months of supervised field work should be required in the training of all health educators. There are advantages in having this field work prior to the completion of graduate training in public health. The prospective student learns the nature of the work and something of his aptitude for it. His professional courses will be more meaningful to him. However, the field work may properly be taken after the

completion of the formal courses, before the awarding of the degree.

V. PERSONAL QUALITIES

A candidate for a position as health educator should possess such personal characteristics as creative ability, leadership, good personal health, good judgment, pleasing personal appearance, common sense, and adaptability. Such important characteristics, along with the ability to size up and meet situations, and the ability to present pertinent facts simply and effectively, are not guaranteed by academic records in formal courses of instruction. The health practices of the health educator himself are also important. Study and improvement in methods of determining aptitude of the prospective students for this profession are needed.

VI. LENGTH OF THE TRAINING PERIOD

If one were to enter upon a program of planned study in the first year of university life, this essential training for public health education could not be secured in less than five years. Study beyond this point would be desirable, especially for those aiming for positions of larger responsibility. If such a five year program were followed, the essential basic preparation could be obtained by a four year course leading to a Bachelor's degree in health education or one with major emphasis upon: (1) the basic and health sciences, (2) education and educational psychology, and (3) the social sciences.

The content and extent of the graduate work required would vary according to the amount of undergraduate preparation, the interval between undergraduate and graduate study, and the quality and type of experience the individual has had. But, including the three months of supervised field training, the very minimum of time required for this training would be twelve months following the Bachelor's degree.

From the standpoint of the work to be done, a considerable degree of professional maturity is needed. Usually only one community health educator is employed in a health department or volunteer agency, so that he is responsible for the program rather than being a staff member in his first position. This demand for maturity explains in part why many mature persons have, through further study, transferred to health education from allied fields. If salaries in community health education can be made commensurate with the expanded opportunity for service we may expect to recruit many able students from among the best high school teachers of health or science who have demonstrated interest, aptitude, and ability in developing community activities. There is need for other positions or field opportunities leading toward community health education and from which we may recruit trainees.

In those institutions which offer a doctorate in this field the usual three years of study after the Bachelor's degree are required. Roughly there is one year of study in education, one year in public health, and one year in research.

VII. THE PLACE FOR GRADUATE TRAINING

Most of the accredited schools of public health offer training for community health educators. They offer to the student a staff of experts in public health and health education together with the opportunity to work with students who are entering other specialties in public health. They are the only institutions in which public health training has been standardized. At present these schools cannot accept enough students to meet the need for community health educators. There is urgent need for the expansion of these facilities or the accrediting of graduate courses elsewhere. Certainly they do

not now have room to train (in co-operation with the school of education in the same university) the needed school health educators. It is expected that, for the present at least, most school health educators will be trained in schools of education with special facilities and staff for a curriculum in school health education.

Programs of professional study in health education can best be offered in those institutions which are providing professional education in other fields of public health and which have instructional facilities in the other areas of knowledge required. Field training stations should be available for all students in health education.

COMMITTEE ON PROFESSIONAL EDUCATION

W. P. SHEPARD, M.D., *Chairman*
 REGINALD M. ATWATER, M.D., *Secretary*
 GAYLORD W. ANDERSON, M.D.
 W. W. BAUER, M.D.
 ROBERT D. DEFRIES, M.D.
 ROY J. MORTON, M.S. (Eng.)

THE NATIONAL HEALTH ASSEMBLY OF 1948

THE National Health Assembly, which met in Washington on May 1-4, under the chairmanship of Federal Security Administrator Oscar R. Ewing, faced two serious handicaps—shortness of time for preparation of the program and the danger of political repercussions in an election year. These two handicaps were overcome with remarkable success.

Some 850 persons attended the Assembly, representing a wide diversity of professional and public interests; and including the American Public Health Association, the American Medical Association, the American Dental Association, the nursing organizations, the farm groups, the labor unions, the women's clubs, and many more. The object of the Assembly was to outline a program for health advance during the next ten years. It worked through fourteen well organized and active sections covering the needs for professional personnel, for hospital and health center facilities, for medical care, for local health needs, and for research in the health field; and the preparation of programs for maternal and child health, rural health, dental health, mental health, nutrition, environmental sanitation, care of the chronic diseases, rehabilitation and general state and community planning for health.

The reports of the various sections were ably summarized at the closing session by Quincy Howe of CBS (see page 858)—an innovation which might well be followed at similar meetings; and the major resolutions will be made available for the public in printed form. No startling new facts were brought out and no ambitious trails were mapped out for the future. Goals accepted by intelligent public health experts were, however, clarified and buttressed by effectively marshalled evidence indicating the need for increased knowledge of basic facts, better machinery, ampler provision of personnel funds. A few controversial issues, particularly federal compulsory insurance, were recognized as not commanding unanimous support; but the really astonishing thing about the conference was the relatively large area of agreement. The panel on Medical Care, for instance, chaired with the greatest skill and wisdom by Dr. Hugh R. Leavell, unanimously adopted the following recommendations:

1. Adequate medical service for prevention of illness, care and relief of sickness, and promotion of a high level of physical, mental, and social health should be available to all without regard to race, color, creed, residence, or economic status.
2. The principle of contributory health insurance should be the basic method of financing medical

care for the large majority of the American people, in order to remove the burden of unpredictable sickness costs, abolish the economic barrier to adequate medical services and avoid the indignities of a "means test."

3. Health insurance should be accompanied by such use of tax resources as may be necessary to provide additional
 - a. Services to persons or groups for whom special public responsibility is acknowledged and
 - b. Services not available under prepayment or insurance.
4. Voluntary prepayment group health plans, embodying group practice and providing comprehensive service, offer to their members the best of modern medical care. Such plans, furthermore, are the best available means at this time of bringing about improved distribution of medical care, particularly in rural areas.
5. The people have the right to establish voluntary insurance plans on a coöperative basis and legal restrictions upon such right (other than those necessary to assure proper standards and qualifications), now existing in a number of states, should be removed.
6. High standards of service, efficient administration, and reasonable costs require:
 - a. Coördination of the services of physicians, hospitals, and other health agencies in all phases of prevention, diagnosis and treatment;
 - b. Effective coöperation between the providers and the consumers of such services.
7. A medical care program itself will not solve the health problems of the nation. It must be coördinated with all efforts directed toward providing the people with adequate housing, a living wage, continuous productive and creative employment under safe working conditions, satisfying recreation and such other measures as will correct conditions that adversely affect the physical, mental, and social health of the people.

These resolutions—with many adopted by other sections—represent a major step forward along the road to better health for the American people. The endorsement of the principles of group practice and group payment embodied in the resolutions quoted above are almost identical with the recommendations made by the Committee on the Costs of Medical Care in 1932. Their adoption by representatives of the A.M.A., of the Physicians Forum, the C.I.O., and the Cooperatives in 1948—that is something new and something of the first importance. The Health Assembly did not register any dramatic victory over the twin foes of poverty and ignorance; but it did close the ranks of the health army for definite progress in a unified advance toward immediate goals. The Health Assembly was described by one delegate as "Democracy in Action." This was an apt characterization. As a result of these four days the public health worker and his various professional allies have been brought into a closer and more intimate contact with the consumer groups than has ever been accomplished before. The team work developed in the Health Assembly has real promise for the future.

WHAT IS EPIDEMIOLOGY?

SIX years ago,¹ we asked in these columns the question "What and who is an epidemiologist?" The answers were fruitful; but they were necessarily related mainly to the type of practical service rendered by the physicians employed in a health department in tracking down specific epidemics of disease. At that time, W. L. Aycock² suggested that a more vital question would be "What is epidemiology?"

This problem seems specially pertinent today. There are two major lines of approach to the basic theoretical knowledge on which applied epidemiology must be based. One is experimental study in the laboratory—the other observational study in the field. The avenue of laboratory approach has yielded brilliant results, and in recent years has tended to dominate the field. It has distinct advantages. In the laboratory, we can—in large measure—hold all factors constant except the

one we are studying and this makes determination of its influence definite and precise. There is, however, an inevitable disadvantage. The controlled factors may actually be of vital significance in nature; and by their elimination we may reach conclusions which do not at all correspond with the complexity of actual phenomena in the field. Both approaches are essential.

The contributions of field epidemiology were outstanding in earlier days. Snow and Budd had no laboratories; but, long before Pasteur, they laid a firm basis for the epidemiology of cholera and typhoid fever; and they deduced from field observations almost all the properties of those causative factors in these diseases which were later to be observed under the microscope. Hirsch, in his *Handbook of Geographical and Historical Pathology*, understood clearly the relation of malaria, first to "a material and specific poison generated in warm climates and seasons," related to organic decomposition; and, second, to "the degree of atmospheric moisture or of the atmospheric precipitation that results therefrom." He even knew that "wherever malaria is endemic at more or less considerable elevations, the seat of the disease is always a valley with a small declivity or a basin-like depression in a plateau"; and that "we find malaria exceedingly common in small and often definitely circumscribed spots by the sides of lakes, small streams or brooks, pools, ponds and ditches." H. R. Carter, by his field observation of the fact that the vicinity in which a case of yellow fever had occurred became infective only after a period of 2-3 weeks, laid the basis for Reed's conclusive experimental approach at Havana.

Theobald Smith, himself a laboratory experimenter of supreme genius, pointed out that inference from field observation "looks at things in nature, describes and compares them, and deduces from such comparisons certain underlying concepts. The experimental method takes the same phenomenon and tries to check or limit all but one of the activities entering into it so that this one activity can be observed, recorded, measured, and weighed. . . . Both methods have their special advantages and disadvantages . . . the experimental method must not let too many machines get between it and the whole and must find some way of putting the fragment surgically removed for experimental purposes back into the whole"; and "the comparative method is frequently in position to restrain the generalizations deduced from experimental procedures and to keep the experimenter from steering away from the goal, which is an understanding of totality."³

A particular problem has reached the stage of experimental investigation only when field observation or prior experiment has indicated the exact question to be asked. Before each fruitful experiment, there must be a hypothesis; and the formulation of this hypothesis is perhaps the most important and exciting event in scientific thinking. It is courage and vision—checked for fundamental soundness—in developing pregnant hypotheses which seems a somewhat rare quality in present-day epidemiology. W. H. Frost, one of the greatest of all American pioneers in this field said: "Epidemiology is something more than the total of its established facts. It includes their orderly arrangement into chains of inference which extend more or less beyond the bonds of direct observation." To this sort of epidemiological thinking, Aycock and his group at Harvard have made notable contributions during recent years.

The pitfalls in the path of sound epidemiological thinking are many. We must, first of all, face the fact—obvious but often forgotten—that the entities with which the epidemiologist deals are epidemiological and not clinical in nature. There is no more serious fault in our practical defenses against communicable

disease than our habit of dealing with scarlet fever and septic sore throat and otitis media as different clinical entities (as they are) but not as manifestations of one epidemiological entity, which is the important aspect of truth to the health officer. On the other hand, Aycock⁴ has pointed out that in one clinical disease, Landry's paralysis, the same pathological findings may be due to a wide diversity of causal factors. He suggests the bold hypothesis that—diverse as the so-called causative agents are in this case—they may perhaps operate upon the tissues through the same biochemical mechanism. He cites the extraordinary case of a strange epidemic at Durban, which was considered by various clinicians to be poliomyelitis, and ginger paralysis and tick paralysis and the Guillain-Barré syndrome. It proved on careful epidemiological study to be due to cooking oil contaminated with tri-ortho-cresyl phosphate.⁵ Certainly, where epidemiological phenomena can be reduced to terms of biochemistry (as has been the case with diphtheria and tetanus) the road to practical control will be opened in a startling fashion. Such studies as have recently been made⁶ on the histological reactions of embryonated eggs to influenza virus may perhaps open the way to understanding of the biochemical, as well as the histological, reactions involved.

Our problem is complicated by the splitting up of many so-called "species" of pathogens into serologic "types." Aycock⁷ is skeptical of the importance of such types in comprehending the basic principles involved, although, of course, recognizing their importance in studying a particular epidemic episode. He says that "with the exception of meningococcal meningitis, there is no instance of any degree of correlation between a single serological type and a single disease process."

Even if the chemical processes involved in pathological reactions to an invading germ were identified, it would still be important to realize the complexities involved in the answers given by the human body to the insults offered by foreign invaders. We must never be blinded by the over-simplified conception that we may discover the cause of any disease. The tuberculosis bacillus is not *the* cause of tuberculosis. It is *a* cause of that disease. You cannot have tuberculosis without the *Mycobacterium*; but half the people whose tissues have been invaded by the *Mycobacterium*, as shown by tuberculin tests, suffer from no disease in a clinical form, although they no doubt show minor pathological reactions to the invader.

Inherent "vital resistance" plays an important role in every departure from normality sufficiently marked to be labelled as "disease." We rarely know what this means; but we do know that it means different things in different diseases; and that it is a factor of major importance. Read the accounts of the attempts to climb Mt. Everest and note the different reactions of different individuals to extremes of cold and to fatigue. Study the records of accident-prone industrial employees and accident-prone automobile operators, and realize the important role of neuro-muscular balance in so apparently simple a phenomenon as a mechanical accident. In the clash between a human body and an invading germ, the differences between individuals in the field of biochemistry are equally significant.

Nutrition may be, in many instances, a vital factor in the defensive mechanisms of the body. In this regard, many students of the problem will not agree with Aycock. He concludes⁸ "that vitamin deficiency as a factor in susceptibility to infection is not a general epidemiological principle. The indications are that only deficiencies of certain vitamins affect susceptibility to certain types of infections and that these occur only in limited areas where these vitamin deficiencies reach a sufficiently severe degree to produce tissue changes which are favorable sites for secondary infection." This may be true if the conclusion is limited to

vitamin deficiencies and to the actual process of invasion by pathogens. We doubt, however, whether prevalence of typhus fever in times of famine is due only to poverty and increased infestation with lice (as suggested by Sigerist⁹); and in tuberculosis, the relation of starvation to increased morbidity and mortality seems highly significant.

Perhaps Aycock's most impressive practical contribution to the science of epidemiology lies in his emphasis on the importance of the influence of climate and seasons on the prevalence of disease. It is strange how this relationship has been neglected since research in epidemiology has been limited to the laboratory and has ignored the area of field experience. The winter incidence of upper respiratory infections is the most outstanding challenge in the whole science of epidemiology.

In those diseases which are disseminated by a specific arthropod vector, the influence of season is obvious and clearly recognized. Aycock¹⁰ demonstrates a beautiful case of four widely different seasonal curves for tularemia (with peaks varying from April to November) depending on the particular vector involved. What is commonly ignored, however, is the peak of intestinal diseases in hot climates and seasons and of respiratory infections in cold climates and seasons. It seems clear that in these instances the phenomena cannot be explained by influence on the parasite but must be sought in the physiological status of the human host. The fact that Dick and Schick tests in warm climates show the same infection rate as in cold climates, with an insignificant rate of clinical disease, is proof-positive on this point. North, many years ago, suggested that one very simple factor of seasonal physiologic variation was the relative distribution of blood supply to the intestinal and nasopharyngeal mucosa at different seasons.¹¹ Aycock, in the paper cited above,¹⁰ gives striking examples of seasonal ebbs and flows of physiological status (iodine content of the thyroid gland, organ and gland weights, resistance to acetonitrile poisoning, etc.). In a later communication¹² he presents a striking study of the amplitudes of seasonal fluctuation in various epidemic diseases and reaches the following conclusions: "Three distinct patterns of amplitude of seasonal variation are found in a number of infectious diseases. In upper respiratory bacterial infections as a group, the amplitudes suggest the operation of a single arithmetic variable consistent with seasonal variation in susceptibility. In a second group, comprising diseases transmitted by intermediary means, the amplitudes are consistent with seasonal variation in the virus reservoir. In a third group comprising upper respiratory virus infections, the amplitudes lead to the inference that both seasonal fluctuations in susceptibility of the human being and in the virus reservoir are determinants."

It has been suggested¹³ that the formula for a case of clinical germ disease may be written as follows:

$$A (a_1 a_2 \dots a_x) - B (b_1 b_2 \dots b_x) = C$$

Letting A = the power of the germ to produce disease

$a_1 a_2 \dots a_x$ = various factors increasing the transmissibility (polluted water or milk, flies, mosquitoes, etc.) or the virulence of the germ

B = the power of the human host to resist disease

$b_1 b_2 \dots b_x$ = various factors increasing the resistance of the host (age, specific immunity, nutrition, etc.)

C = a clinical case of a germ disease (or the absence of such a case if the resultant of the factors in the opposite half of the equation falls below zero)

The task of the practical epidemiologist is to concentrate on the weakest links under A (elimination of mosquitoes, pasteurization of milk, purification of water, use of antibiotics, etc.), or on the factors under B which are most easily strengthened (through specific immunization, improved nutrition, personal hygiene and the like). The function of the theoretical epidemiologist is to study all the possible factors in such an equation and to evaluate their relative importance.

THE COBBLER'S CHILDREN

ONE may logically ask why the question of routine chest x-rays for all admissions to general hospitals should be a subject for discussion at this time. The public health significance of a procedure which can be used to determine the presence of disease of the heart or lungs in 16,000,000 hospital admissions annually needs no emphasis. The advantages to patient and hospital staff, the usual findings, the technical methods available, their respective cost, even ways for financing such a program, have all been determined and have been widely publicized.¹ The fact still remains that in 1948 less than 3 per cent of the more than 6,000 hospitals in this country were on record as having adopted x-raying of all admissions as a routine procedure,² despite the fact that about one-fifth of all deaths from tuberculosis occur in general hospitals.

With these considerations in mind, a brief summary of the present status of routine hospital admission x-ray service would seem pertinent. It is generally recognized that a chest x-ray is as important a part of the routine for every hospital patient as a blood count, serology, or urine examination, and will reveal the presence of unsuspected disease more often. Numerous studies have shown that approximately 2 to 3 out of every 100 admissions to general hospitals will have x-ray evidence of tuberculosis. Half of the cases will be active, a rate at least twice that found in the general population. As many more patients will show other types of pulmonary pathology or evidence of cardiac disease. These are individuals already in hospitals, physically and psychologically receptive to treatment. To cure such a patient of a minor infection and discharge him with still undiagnosed active pulmonary tuberculosis is hardly in keeping with the highest traditions of medical care, and certainly in no way consistent with the ideals of public health.

The routine chest x-ray of all admissions to general hospitals serves a no less useful purpose in the protection of the members of the hospital staff. A higher rate of tuberculous infection has been consistently found among doctors, nurses, and attendants in general hospitals as well as tuberculosis hospitals, compared with groups of similar age, sex, and race composition not so employed. The

presumption is strong that the source of their infection may be the patient with undiscovered tuberculosis. Medlar's recent studies³ would certainly lend weight to this hypothesis. The constantly increasing proportion of non-reactors to tuberculin among adolescents and young adults further accentuates the danger of such exposure in hospital personnel. Even if we disregard the important factor of the hospital's human responsibility for the safeguarding of the health of its employees, the desirability of maximum protection for staff in these days of personnel shortage remains. The cost of compensation, which is being awarded in a steadily increasing number of states to hospital employees who contract tuberculosis in the course of their employment, is an additional consideration.

Equally explicit information is available as to technical methods and costs. There is no one method universally applicable to all situations, and the technique to be employed will depend on the daily hospital admission rate and the space and facilities at hand. For larger institutions, with admission rates of more than 25 patients daily, some type of miniature film equipment has been recommended. Full size film is advised for hospitals with fewer daily admissions. The initial outlay for a photo-fluorographic unit is high, \$5,000 to \$12,000, with an overall cost per film of approximately \$.50. Large films can be taken with little or no additional equipment, but each x-ray will be more expensive and an additional burden will be thrown on the technical staff. A satisfactory compromise for institutions admitting approximately 25 patients daily is the magazine cassette,⁴ which has been employed by the chest clinics of the New York City Department of Health since 1943. This unit operates like a roll camera, requiring reloading only once for every 50 exposures. It is rented for a nominal fee and uses full size paper film in rolls of 50, at a cost much less than that of celluloid film. The interpretation of the x-rays, the follow-up examination on suspicious or definite cases of tuberculosis or non-tuberculous disease, and the necessary record keeping present no unusual difficulties, and are readily incorporated into the hospital routine.

The financial problems involved in securing the equipment can be met in several ways. The hospital may pay for the unit itself. In many areas the city or state health department may be willing to furnish the apparatus, particularly if the latter is in a position to utilize federal funds for the purpose. The local tuberculosis and health association, chamber of commerce, hospital auxiliary, or other good friend of the hospital may make such a contribution. Once the unit has been procured, the cost of its operation, which should not exceed \$1 per patient, can be readily met. In private institutions it is usually added to the patient's bill; in public institutions, to the budget.

The most serious drawback to the extension of the practice of routinely x-raying all admissions to general hospitals has been the difficulty in manufacturing photo-fluorographic equipment rapidly enough to meet the demand. Production is now increasing steadily, delays in filling orders are growing shorter, and this explanation will soon be an excuse rather than a reason. Unless the general hospitals of this country are prepared to carry out their responsibility for this program they may find themselves regarded in the same category as the cobbler in the old proverb whose children always had holes in their shoes.

Report to National Health Assembly

QUINCY HOWE

Columbia Broadcasting System, New York, N. Y.

THE following stenotypist's report in the style of a radio commentator was a feature of the final session of the National Health Assembly.

The most human of all human interests has drawn us together here in this National Health Assembly. It is the interest in what most of our forefathers called, and many of us still call, the temple of the soul. After all, nothing affects us more personally and more directly than the health of our bodies.

Human nature has therefore played a big part in all of the section meetings of the National Health Assembly, and it is going to play, I think, a still larger part in the summary that I am to present on the work of these sections.

It is human nature for us to want to help others; it is human nature for us to believe that we are right; it is human nature to make mistakes. I have the layman's admiration for the medical profession. I think our doctors are primarily motivated by the desire to help other people. I suspect some of the rest of us may be motivated by more selfish considerations. But, selfish or unselfish, we are reluctant to believe that we are wrong and that the other fellow may possibly be right.

It is the great achievement of this assembly that so many different experts in so many different fields have reached agreement on so many subjects. Just how correct these agreements may be, we shall perhaps learn before the ten years for which we are planning have run their course.

When Mr. Ewing invited me to summarize your findings, I am sure he

wanted to give you a final reminder that it is human to make mistakes. So far, you have seen human nature at its best. What you are about to hear will remind you how fallible human nature can also be. But perhaps my years with the Columbia Broadcasting system will come to my aid. CBS, you see, makes it a policy not to permit news analysts to go in for special pleading on the air. We are told to present our material in such a way that listeners can draw their own conclusions, so it is in that spirit that I am addressing myself to my present task.

The radio industry seems to operate on the assumption that most Americans no longer know how to read. Perhaps I should say that the radio industry is simply making a valiant effort to make reading quite unnecessary. I am not going to operate on that assumption, though, today. I am going to assume that all of you here, all of you, not only know how to read, but do read. I shall also assume that all of you have read, will read, or at any rate can read the conclusions that the 14 sessions of the National Health Assembly have reached in their reports.

Instead, therefore, of summarizing these reports in detail one by one, reports that speak so eloquently for themselves, let me just point out certain common denominators in these reports, and then single out a few striking specific points in the individual reports.

Finally, I will try to suggest a few broad conclusions that seem to me to arise from this material.

Now, there is one common denominator, a very human common denominator, that struck me with special force in every one of these section reports. It is this: Each section regards its own field as fundamental, basic, all important, indispensable. And in each case, the logic behind these section reports seems to me absolutely unanswerable.

For instance, who can possibly disagree with Dr. William C. Menninger and the Mental Health Section when they tell us that more than half of all our sick people, inside and outside our hospitals, suffer from some kind of mental ailment? No one can dispute the statement of the Dental Health Section, that dental caries, tooth decay, is the costliest disease known in civilized man. Perhaps some of you would like to challenge Dr. Haven Emerson and the Local Health Units Section when they say that our people can't possibly expect to enjoy better health unless and until they organize themselves into more efficient local health units. Certainly he wouldn't find any disagreement from Dr. Florence R. Sabin and the Community Planning Section. They would agree with him when they tell us that the community must do a lot more planning for its own health.

And in another section, you know that the child is father of the man; the mother is the source of all human life, as Dr. Leona Baumgartner and the Maternal and Child Health Section have explained. But to have healthy children, we have got to have healthy and also properly educated grown-ups, and Dr. James R. Miller and his section on the Chronic Disease and the Aging Process explained this when they pointed to the need, the growing need, for better care for our growing generation of old folks.

Then, Mr. Joseph W. Fichter and the Rural Health Section explained why

Americans who live on farms have every reason to consider themselves second-class citizens in so far as medical care is concerned. When you think of that, you wonder about the permanently handicapped and the crippled, veterans and non-veterans, for whom Dr. Henry H. Kessler and the Rehabilitation Section made their appeal.

Then we hear Dr. F. G. Boudreau and the Nutrition Section prove beyond any possibility of doubt that better nutrition is the real answer to better health. Then Mr. Arthur D. Weston, and the section on Environmental Sanitation come along, and they make out an equally unassailable case for better sanitation, purer food, a healthier environment, and, of course, Dr. Algo D. Henderson and the Medical Personnel Section explained the big thing we really need is more and better trained doctors and nurses, and especially assistant personnel. It is also just as true as Dr. Andrew C. Ivy and the Research Section's conclusion that we need more and better advanced research and teaching.

And then Dr. Charles F. Wilinsky, in the Hospital Facilities Section, called attention to the shortage of hospitals and other physical facilities.

Dr. H. R. Leavell in the Medical Care Section perhaps had the toughest assignment of all. He had to get his section to agree on the most controversial single issue before any of the sections: What needs to be done to give the American people the better medical care that they clearly require?

Well, so far I have stressed the differences in all these section reports, but my purpose hasn't been to suggest that they conflict with one another. Rather, I have tried to show how wide a variety of subjects this National Health Assembly has covered. Moreover, it seems to me that the subjects the Assembly has covered do not conflict at all; they overlap. I believe "impinge" is the correct word.

And most of all, they complement and even duplicate each other, complement as well as compliment each other. The need for more and better research, for instance, is a universal need. It goes through all these sections. A good local health unit is going to interest itself in the care of both the young and the aged. It is going to interest itself in mental as well as dental cases; it is going to interest itself in questions of environment as well as questions of nutrition.

Several of these sections have referred to the question of discrimination against Negroes, but discrimination takes many forms, and the best cure for discrimination, after all, is education.

Here we come to what is perhaps the most important single common denominator in all the section reports. Again and again section chairmen pointed out the need for more facts, more research, more information. For instance, how many more doctors, nurses, and medical personnel do we actually need? What do we need in the way of enlarged hospital facilities?

And these questions tie right in with the question of rural health. The Rural Health Section had a lot more information than the section on Mental Health was able to gather. Perhaps that is because we have had country doctors much longer than we have had psychiatrists, but the country doctor is becoming the forgotten man. To the outsider, it might seem the psychiatrist is getting all the breaks, until we read this report on mental health from the Mental Health Section coming up with its urgent request for much more information in a field that is perhaps more tragically understaffed than any other.

Without going into the whole list of section reports and their details—I will do that later—it does seem possible to draw this conclusion now: Nearly all the section reports, as I say, call first and foremost for more information. Surely it ought to be possible to avoid

duplication and to send out (instead of duplicating with similar questionnaires and investigating trips) the kind of questionnaire, and gather the kind of information that could be cleared through some central agency and made available to all the groups.

And such an information center would meet the cooperation of all these different sections before it set up shop in the first place.

Now, the friendly attitude that all the delegates to this Assembly have shown toward one another, the interest all have taken in one another's work, suggests that you can pool your efforts in compiling and then applying the information that almost all of you seem to need.

To most Americans shortages is a wartime word. To you who are fighting a never-ending war of your own against all the ills that flesh is heir to, shortage remains just as familiar a word as ever.

First, there is the shortage of highly trained personnel, of your doctors, researchers, and specialists in lots of different fields. Then there is the shortage of assistants, especially dental assistants and nurses. Then there is the shortage of medical schools and medical teachers, the shortage of hospitals, and, it seems, above all else, a shortage of cash. How are we going to pay for all the training, all the equipment, all the services that we need? How are we going to make the career of administering to the nation's health a career that does not require superhuman effort, superhuman sacrifice, or else a superman's bank account?

Perhaps it is not so much a question of salaries as it is a question of less costly training and of greater security for those who are financially equipped to practise medicine, go in for research, or engage in related fields of public health.

Leaving to one side the controversial question of federal health insurance, there does seem to be a rather wide-

spread feeling in which several sections have unanimously concurred—a widespread feeling that the taxpayer is going to have to carry some, probably more, of the financial burden that better health service requires.

The Rural Health Section, for instance, is unanimously agreed that the federal government must bear a greater share of the expense of rural medical care. The farming communities, even the farming states, just haven't got the funds. On the other hand, the local health units must rely largely, I suppose, upon local support—perhaps through local taxation, somewhat after the fashion of our schools.

But, can local communities carry the whole load of maintaining and extending hospital service? And if the state in addition to the federal government comes into the picture, what part has the state medical association to play? What representation will the public have?

Dr. Andrew C. Ivy's section on the Nation's Need for Research in the Service of Health recommends fluid funds from federal tax sources. No less important than the need for funds is the need for people. The two go together. Get the money and you can get the men.

I am not, as I said, going to summarize all these section reports. All of you can read them as well as I can, and most of you can understand what you read in the field much better than I can.

The section chairmen did me the honor last night of telling me what seemed to them the high points in their reports, and I will now try to pass on to the whole assembly here the salient impressions that these section chairmen left with me.

The most newsworthy and the most controversial decisions were those reached by Dr. Hugh R. Leavell's section on Medical Care. These decisions were newsworthy because of the wide area of new agreement among the members of Dr. Leavell's section.

All the groups represented in this section agree that prepayment is the best way to finance medical care. That means insurance. All agree that all the American people are entitled to medical care. All agree that federal funds must be used to finance at any rate some of this medical care.

All agree—and this is important—that the people have the right to set up their own health insurance plans. As you know, there are more than 20 states that do not now permit this but insist that the medical associations must control those health insurance plans.

This section of Dr. Leavell's on Medical Care even agreed that the medical care program alone will not solve all our health problems. This was almost a unique example of humility among the various sections.

The only disagreement among the members of Dr. Leavell's Medical Care Section—and I am not trying to minimize this disagreement, because it is an important one, but it was there—is the question: How to prepay medical care? How to take out this insurance? Some say that we should continue the voluntary method and give free care only to those who need it—a kind of a means test arrangement. That is the system now in force and that is the system that the committee, I believe, has endorsed. Others however, in this section say that we must have universal compulsory federal health insurance and that that need is immediate and urgent.

Now, for the high points of some of the other section reports. Dr. Algo D. Henderson's section on Medical Personnel stressed particularly the great need for nurses, also the need for dentists, baby doctors, and specialists in mental ailments. The big problem in connection with getting more people into nursing seems to be, as in so many cases it is the big problem, economic. They need, among other things, better working conditions, and the public needs to

know more about the prospects and the possibilities of a nursing career.

Dr. Charles F. Wilinsky's section on Hospital Facilities put a lot of emphasis on the need for coöperation between all and among all different groups and elements in the community. They made the point that our hospital system has got to be kept extremely flexible.

Dr. Wilinsky was pointing out last night that new cures that medical science may develop—like these new penicillin drugs and sulfa drugs that have so much speeded up cure of certain diseases that used to hospitalize people for a long time—may radically change the needs of the American people for hospital care. Most hospitals are still run by private, charitable, and religious organizations, but more tax money is going to be needed to do a better job.

Dr. Haven Emerson's section on Local Health Units came up with about as drastic a suggestion as any. They simply urged doubling all personnel and facilities in the public health schools—just double them! At once! As a matter of fact, there are only nine public health schools now in the United States; only nine. Perhaps that could be doubled. There is a need, in any case, says this section, for basic reorganization.

Dr. James R. Miller's section on Chronic Diseases and Diseases of Old Age wanted to stress two points in particular. First, they wanted to stress the importance of diagnosis of these chronic diseases and early treatment for them. After all, it is to the interest of our children to keep us members of the older generation in good shape and fit so we can work and our kids won't have to support us too soon and too long.

The second point that Dr. Miller's section made is the stress on the importance of rehabilitation. Experience in the rehabilitation of war veterans has shown what can be done in this direction. There is also rehabilitation needed among older people who can be and have

been cured of some of these diseases that used to be fatal.

Dr. Leona Baumgartner's section on Maternal and Child Health included in their report these words: "A child's feeling about a test in school can produce as important a stomach ache as eating a spoiled custard."

This section on child health and maternal care points especially to the recent decrease in the maternal death rate, but it also points out some rather striking figures and facts. Three out of every five children in the United States live in families that have an income of less than \$2,100 a year. Four out of five children live in families that have an income of less than \$3,000 a year. And between Pearl Harbor and VJ-Day almost half a million American babies died as compared with somewhat under 300,000 of our fighting men.

The child health and maternal care section urges and stresses also the need for spending more money on the medical care of secondary school children. The amount of money now spent on those children by the states, through the schools now ranges between one cent per child per year and three dollars per child per year.

And this section tells us that the general public and even, I dare say, many members of this Assembly, don't know what great changes have occurred in this whole field of child care and maternal health.

Mr. Joseph W. Fichter's Rural Health Section reports, among other things, that it is not possible for doctors to practise such good medicine in country districts, simply for the lack of facilities, and yet, on the other hand, this section points out that a lot of Americans would like to go back to country living, and more doctors might be willing to go back to country living if they had the hospital facilities, the money, and the cultural opportunities that the rural communities do not now afford.

Perhaps it is worth while to find out, says this section report, what the small town doctors themselves have to say about the prospects of rural medical care, rural hospitalization, and the rest.

Dr. Ivy's Section on Research in the service of health, stresses two very familiar needs that run like a theme through almost all these reports, the need for more money, the need for more funds to be derived from taxes.

Now, one of the most interesting features of Dr. Ivy's Research Section report was that they agreed that there is no lack of zeal among the bright young students. They want to go in for medical and all kinds of scientific research. This applies in all branches. Research is the thing that tempts and attracts the top 20 per cent, the people with the best scientific minds, and this top 20 per cent, ten years ago and more, used to go into medical research and all other forms of scientific research automatically, but something serious has happened.

The discrepancy between the salaries that one gets as a research worker and the salary that he can get if he is a doctor in private practice, or the salary that he can get as a scientist in the employ of private industry—this discrepancy is so great, and the uncertainty of the future for research is so great, that a lot of these best brains among our researchers are going into other fields.

Like this whole question of rural health, the answer on this matter of research in the service of health seems to me to be looking into all our folkways and seeing if we can't plan our whole lives somewhat differently.

Dr. Sabin's Section on Community Planning urges, among other things, that we take a very broad view and define health, not just as not being sick, but as a wide and general sense of well-being, including social and economic conditions, as well as the physical condition. They also warn against selling

the people in your community the idea of community health and its importance in various projects until you have the personnel to carry these projects through. All the community must participate in these projects. We need more public health councils.

Dr. Henry H. Kessler's Section on Rehabilitation reminds us that we as people are not so husky as we think. We need to know and hear more about the rather high rejection for physical reasons by the armed services during the war, and we need to break down, and this is a long process, the prejudices that exist against crippled and permanently handicapped people.

Dr. Ernest G. Sloman's Dental Health Section stressed especially the need for more dental schools and more dental research. Dental schools, it seems, need \$500 per student in addition to the tuition that the student pays in order to give that student the proper training. The big need here is for research projects—something about dental research—it does not seem as dramatic as in some other fields of research, and yet an awful lot can be done to cut the biggest part of our medical bill, the bill of the dentist, and this dental program ties in with the whole sanitation program because of the possible use of sodium fluoride in drinking water.

Dr. William C. Menninger's Mental Health Section is pioneering in what seems to me perhaps the most important field of any—maybe because it is new. Here are some figures that they come up with: Thirty to 60 per cent of all patients who consult doctors have emotional disorders that lead to physical disorders; 62 per cent of all the inmates of veterans' hospitals are psychiatric patients; one million of all admissions to Army hospitals during the war were psychiatric cases. There is an urgent need for personnel in this field. It is most important to do something about the state hospitals. We have a tendency to forget

about the inmates and the doctors in those hospitals. These doctors number anywhere from one to 300 patients, all the way to one to 1,000 patients—one doctor, one psychiatric doctor to 1,000 patients in a mental hospital, and outside the hospitals there is only one psychiatrist to every 140,000 Americans as compared to one M.D. to every 750. Barely 1 per cent of our practising nurses have psychiatric training, and they have got to care for half of all the patients. One hundred thousand new beds are needed for psychiatric cases in our hospitals at once, and yet with all this need for beds and nurses, prevention is the only real cure to this psychiatric problem, and the prevention of these mental difficulties and diseases and ailments needs the coöperation of every agency in the community—our teachers, our clergy, our lawyers, our social workers, management, labor, and everyone—it is perhaps the biggest educational job there is. It goes, maybe, to the very roots of our whole way of living.

Dr. Frank G. Boudreau's Nutrition Section says there ought to be a nutrition expert included in every health group; that nutrition is the field in which the most striking advances have been made in the last twenty-five years. We ought to start nutrition work on expectant mothers at the very start of pregnancy. Then we will get better children all through life and a lower maternal death rate. And one point that Dr. Boudreau recalled last night was that during the war, in England, Churchill went to his top scientists and said:

"What is it that must come first on the list?" They said: "See that the British people get first-class nutrition during the war." They got that nutrition, and in spite of having fallen back in many, many other fields, and suffered all kinds of hardships and tribulations, the British health, due to this good nutrition, is better than it has ever been before, and a great part of the explanation, the

way the British have told us, is because of the attention they gave to this matter of nutrition.

Mr. Arthur D. Weston's Section on Environmental Sanitation is important because it stresses the external—the importance of external factors in relation to public health.

Now, before summarizing this summary, and drawing one or two final conclusions from the many I have outlined, I think I have a duty to report on one other matter.

As Mr. Ewing explained, this assembly cannot, under the law and under its own rules, recommend any definite legislation. I do not think this prevents me in summarizing these reports and discussions from touching on the question of the membership of the United States in the World Health Organization. Dr. Louis I. Dublin raised the question yesterday from the floor. He did not press his proposed motion to urge Congress to act because Mr. Ewing said it would be out of order. Mr. Ewing made it clear, and I think it was clear to everyone present, that all members of all sections agreed that whatever our other differences may be, we united in wanting the United States to join the World Health Organization.

Dr. Fishbein, of the A.M.A., has already made two strong public statements, though, to that effect here at this assembly, and I have not heard one dissenting voice, and I have heard an awful lot in praise and agreement. For what it may be worth, perhaps I may raise my voice, too, safe in the knowledge at this time, at any rate, that I am expressing something that everybody here feels agreement about.

And this question of the World Health Organization is not the only matter on which this assembly has reached agreement. As I review the high points of the section reports, the high points that the section chairmen wanted stressed, it seemed to me that this assembly has

come to agreement on a great many important matters—matters on which agreement has not always been possible before.

Perhaps the greatest single achievement of this assembly is that all kinds of public organizations have sat down together and worked out common problems and common programs with members of the medical profession and other scientific groups.

Now, some laymen may feel that the American Medical Association has been somewhat slow in coming around to health insurance and to the idea of government aid for health. But look at it from the doctor's point of view: Like all of us, doctors are creatures of habit, and they have acquired their habits in about the hardest way there is. Just try to change some of your own habits. Try to stop smoking the way I did a little while ago; or try pulling up stakes; try going to live in a new community, changing your profession—it isn't easy.

Those of us who have been impatient with the American Medical Association for resisting change show a sad lack, I think, of understanding of human nature. Doctors have to make so many sacrifices. They submit themselves to so many disciplines, they are so overworked just keeping up with their own jobs, that the wonder to me is that any of them have time for anything else. And it is only natural that those who do interest themselves in something beyond their engrossing daily tasks want to hold on to their own tried and tested way of doing things.

That so many doctors not only have taken the time to work with the National Health Assembly but have shown themselves so coöperative, so understanding, so open-minded, seems to me the most promising and the most important development of this whole meeting. The example that the doctors have set us here should encourage all of us to go on with the kind of work that this National

Health Assembly has only just begun.

Now, there is no question that the high spot of this assembly is the coöperation between men of science and the general public. This coöperation reminds us that the atomic bomb and atomic energy are not so new as we have been led to believe. Everyone said when the atomic bomb went off that now we are in a new age, nothing is the same as it was before, and now the scientist is out of his ivory tower, and now science has got to interest itself in politics and general affairs, and the general public has got to be interested in science.

But even if there had been no atomic bomb, we would have had a meeting like this just the same. It is all a part of the same trend. The atomic bomb is one part of it, and this meeting is another part of it. It is the trend of bringing the scientists out of the laboratory, forcing the laymen to concern themselves with the impact of science on our lives. Here it happens to be medical science.

There seems no doubt that medical science can do the job. The two big questions are: Where will the money come from and where will the people come from? This assembly is hopeful. It is a hopeful sign because it is a sign of the times. It proves that the scientists and the public can work together, with government officials acting simply as intermediaries, but with the funds that finance this assembly coming from private sources. It seems almost the ideal combination of government, free enterprise, of expert and layman.

Now, as a complete and rank outsider, can I take advantage of the tolerance of this tolerant gathering to close with just one mildly critical observation, not so much of this National Health Assembly as of our American way of doing things.

As I said at the beginning, all these section reports call for more and more

facts. Of course, none of these sections has yet got the complete story. That will never be told. Some of them are just beginning to pioneer. All of them need to correlate what they already know. But we Americans, as a people, seem to have a blind passion for facts as facts. We have an almost mystical faith in statistics. Now, the collection of facts is a necessary and rewarding enterprise, but it is not a substitute for action. It is not a substitute for something that is even more difficult than action, and that is thought. Too many of us simply collect facts simply to avoid having to do anything about it. We are like the fanatic who redoubles his zeal after he has lost the sight of his objective.

During the 1920's, a wise Spaniard, Salvador de Madariaga, wrote a book, *Englishmen, Frenchmen, and Spaniards*. He made the point that the Englishman is the man of action, the Frenchman the man of thought, the Spaniard the man of passion. The Englishman, he said, thinks with his knees and elbows; he acts on instinct, and he almost always acts right, although he cannot, possibly tell you ahead of time what he is going to do or explain afterward why he has done it. The Frenchman, on the other hand, can give a perfect analysis of every situation, but when the moment to act comes, he is mentally muscle-bound and has a hard time putting his ideas into practice. Afterward, however, he can always give a perfect explanation of just exactly what happened.

Now, if the Englishman is a man of action and the Frenchman is a man of thought, the American seems to me a man of fact. Where the Englishman puts all his energy into action, we put all our energy into collecting data. Where Frenchmen put all their energy into theory and logic, we put all our energy into accumulating facts.

This is not a tendency that is peculiar to science. I think my own field of radio is the worst offender. Have

you ever seen a market survey, a listener's survey, a breakdown of Hooper ratings? I am going to take a chance now. It is no accident that Dr. Stanton, president of the Columbia Broadcasting System, one of the sponsors of this National Health Assembly, is himself a statistician.

Now please do not misunderstand me, and I hope Nate Halpern, Dr. Stanton's deputy at today's session, won't misunderstand me either. All I am saying is that a great many Americans are completely fascinated by facts. Obviously the American radio could not be where it is, and the American science could not be where it is if our leading people in these fields had not devoted themselves to the pursuit of facts, facts, facts.

But I am not saying anything to this assembly that I would not say to the president of the great organization for which I work if I say that the mere accumulation of facts is not an end, an aim in itself. It is what we do with the facts; it is what we make the facts mean that really matters.

I am not going to tell you people what all the facts that your various sections have gathered together mean. I don't know. But I am sure a lot of you do. In some of the fields that your sections have covered you will, of course, want to go out and gather more facts. Rightly! But in other cases I am sure that you have enough facts to spell out some answers; and in still other cases I bet you know the answers already and your next step is to do something about them.

It is not, however, part of my function to tell you what to do or what conclusions to draw. It is my function to review some of the material that has come before you. I will feel I have done my part if what I have said leads you to continue in thought, in action, and in spirit, the many tasks you have set yourselves and our people.

Clearing House on Public Health Salary Information

CALIFORNIA STUDIES LOCAL SALARY TRENDS

THE California State Department of Health, through its Division of Local Health Service and at the request of Local Health Officers of California, has released two salary studies covering full-time professional and technical personnel in local health departments of the state. These studies are as of October 1, 1947, and as of January 1, 1948, respectively. The October study includes 34 local departments, the January one, 32, but only 25 departments are common to both studies. A total of 40 jurisdictions are included in one or both studies.

In no instance were salaries decreased between October, 1947, and January, 1948. For the 25 health officers in both studies actual salaries paid or range of salaries, 13 remained stationary, and 12 increased during the 3 month period. In 5 instances the increases were less than 10 per cent, but in 3 they were more than one-third. The highest monthly salary of \$1,125 remained unchanged.

One more example: of 22 chief sanitarians reported at both dates, salaries of 14 remained stationary; those of 8 increased. The increases were less than 10 per cent in 4 instances, and 11, 16, 27, and 41 per cent respectively, in the remaining 4. A detailed study of this material might well reveal that variations in the extent to which salaries were increased among the separate professional groups, bear a close relation to the separate pressures brought upon them to accept other positions.

The relationship between health officers' salaries and the populations of

their jurisdictions is also worth examining. Of the 40 jurisdictions reporting salaries for either October or January or both, 13 had 1940 populations of less than 50,000; in 8 of these the health officer's monthly salary was \$600 or more. Of the 10 whose salaries were less than \$600, 5 served small populations, but 5 served populations of from 50,000 to 250,000. Again it is difficult to sort out exact correlations, particularly in view of the erratic population changes in California since 1940. Nevertheless, these figures bear careful analysis in the development of criteria for setting salary scales. They also pose the perennial question of whether the best use is currently being made of the professional and administrative skills of the public health officer in a population of 30,000, for example.

Perhaps one more word needs to be said. California is among the more fortunate states in having a comparatively low vacancy rate in its local health officer positions, the fruit, in part, perhaps, of such current studies.

LOCAL HEALTH DEPARTMENT SALARY STUDY

The May *Journal* (p. 714) reported a plan to include a sampling of local health departments in the next study of public health salaries. This study, sponsored by the Association of State and Territorial Health Officers, is already under way. The questionnaires have been prepared and sent out by the Committee on Professional Education; the technical work of analyzing and tabulating the material is being undertaken by the U. S. Public Health Service.

Questionnaires have gone to a rari-

dom sample of 126 jurisdictions in 39 states representing all areas of the country. One-fifth of the jurisdictions are state health districts. The study is limited to health departments serving from 50,000 to 250,000 persons.

LOUISIANA TAKES STOCK OF ITS SALARY SITUATION

In January, 1948, the Louisiana State Health Department made a telegram survey of salaries for 30 classes of positions common to state health agencies. Nearly every state replied to the Louisiana questionnaire; the largest number reporting for any category of workers was 43 for director of public health nursing; 42 reported on the director of public health engineering.

Except for the state health officer, salaries in the upper grades of positions appear to be somewhat higher in Louisiana than the average for all states; in the lower grades of positions, they are distinctly lower. For instance, Louisiana ranks 9th among 23 grades of minimum salaries for director of local health administration in 37 states, and 6th in 27 grades of maximum salaries for this position. For public health physicians at the entrance level it ranks 18 among 21 grades of minimum salaries in 28 states, and 14 among 23 grades of maximum salaries.

This study is available from Dan S. Moore, State Director of Personnel, Louisiana Civil Service Commission, Capitol Annex, Baton Rouge 4, La.

CONVINCING A BOARD OF ESTIMATE

In New York City the district health officers of the Department of Health have organized themselves into a Health Officers Council. This organization is

similar to the Conference of Local Health Officers of a number of states.

In April, this Health Officers Council presented a memorandum on salaries to the New York City Board of Estimate. This memorandum pointed out that of 21 health centers covering the 31 health districts of the city, only 13 were administered by health officers qualified according to Civil Service standards; of the 13 only 8 had health department experience. It also pointed out that 8 experienced health officers had left the department in 1947; of 12 carefully selected candidates who received a year's training in a school of public health through federal funds and several months of intensive training in the department, only 5 remained.

The Health Officers Council cites these facts as illustrations of the situation existing with respect to all types of workers in the health department. It believes that the unfavorable salary situation is the basic reason for the failure to maintain department personnel up to strength.

By way of highlighting its argument, the Health Officers Council compares the salaries and the population served of the New York City district health officers with those of 8 neighboring urban areas in New York State and with 10 health jurisdictions in California. This state was chosen because figures were available and because California and New York State are comparable as to per capita wealth.

This memorandum might have suggestions for other areas in their dealings with appropriating bodies. A limited supply of the memorandum is available from the Health Officers Council, 125 Worth St., New York, N. Y.

SANITARY ENGINEERING AND NATIONAL SECURITY

"A Preliminary Report—Sanitary Engineering Aspects of National Security" by the Subcommittee on Sanitary Engineering Aspects of Major Catastrophes of the National Research Council, has now been made available for general study. Prepared for and at the request of the Committee on Sanitary Engineering and Environment of the Division of Medical Sciences of the National Research Council. The Introduction states:

"This report deals with some of the sanitary engineering aspects of major catastrophes primarily as affecting the civilian population. It presents statistical data concerning catastrophes during the last quarter of a century resulting from natural phenomena and man-made causes. It gives emphasis to the special hazards of the future in the light of technological developments in the arts of peace and war and recommends organization of sanitary engineering services to mitigate the effect of future catastrophes and to provide for control and relief measures when they do occur."

"We must make adequate preparations for meeting the emergency sanitary engineering problems associated with natural catastrophes; in addition it is necessary to develop an organization capable of orientation to the contingency of war, while functioning efficiently in times of peace."

The report points out that a well coordinated program of national security to safeguard public health, welfare and our economic potential should include a plan and organization for sanitary engineering activities. The scope of the activities applies particularly to protection and promotion of public health through control measures over the environment in which people live and work. This specialized service and responsibility includes such essential community or regional facilities or services as: water supply, sewerage, control over atmospheric and stream pollution, insect and rodent control, sanitation of food production, processing and distri-

bution, garbage and refuse collection and disposal, sanitation as related to housing, industry, ventilation, swimming and bathing and general community life, and related matters.

Examples of the type of catastrophe in which sanitary and public health engineering play an important role include the general economic prostration which occurred in England during the winter of 1946-1947 due to the unusual snow storms, high winds and floods; the widespread floods which occur in the Missouri and Mississippi River valleys; and the recent Texas City explosion. The committee has classified possible disastrous events into 3 categories: those of natural phenomena such as floods, tidal waves and earthquakes; the man-made accidents which would include explosions, fires, and epidemics; and war hazards, including aerial warfare, atomic bombing, sabotage, and destruction or deterioration of essential civilian facilities.

In the past, the American Red Cross is cited as being the principal disaster relief organization on a national level. According to the report, for the 26 years from July 1, 1920, to June 30, 1946, \$105,000,000 were spent by the A. R. C. in giving disaster relief. Statistical data on the major disasters during that period are included in a separate table. Another tabulation to show the seriousness of major disasters in the United States includes 38 instances during the period 1865-1945 in which a total death toll of 29,622 is listed. A summary and classification prepared by the Metropolitan Life Insurance Company showed that 919 catastrophic accidents occurred during the period, 1937-1946, and listed 12,987 deaths. Data on these events are likewise covered in a special table.

Recommendations include:

"Calamities due to natural phenomena or man-made accidents, or those resulting from acts of warfare such as direct enemy attack or sabotage, involve a wide range of sanitary engineering problems. A consideration of these basic factors indicates that planning for prevention and control over major disasters should originate at a high federal level and be worked out in such detail as to reach down to each community in the nation."

Specific recommendations include:

1. Considering the importance of environmental sanitation in disaster relief work and national security, the committee recommends that special provision be made to develop sanitary engineering programs within the national disaster relief and security program and to place responsibility for them in qualified sanitary engineers.
2. The committee recommends that, in all research and development work of the federal government, channels be established through which the point of view of the sanitary engineer may be obtained. This may be done through employment of qualified consultants or the appointment of one or more full-time sanitary engineers on the staff of the agency or agencies concerned. Agencies in particular need of the full-time services of sanitary engineers are:

American Red Cross
Atomic Energy Commission
Central Intelligence Agency
National Security Resources Board

3. The Sanitary Engineering Division of the Public Health Service, by reason of its specially trained staff and established relationship with the sanitary engineering divisions of state, county, and local departments of health, is particularly well qualified to serve as a liaison unit between federal agencies and those of the respective states and their instrumentalities.

4. The committee recommends that a permanent sanitary engineering unit should be organized in the Public Health Service to carry out disaster and national security activities.

Working with the National Security Council, Central Intelligence Agency, National Security Resources Board, the National Military Establishment, the American Red Cross and various other federal, state, and local agencies, this unit would perform such functions as:

- a. Coördinate sanitary engineering work between federal, state, and local agencies, with special emphasis on mitigation of hazards to civilians in times of peace or war.
- b. Develop plans in consultation with an overall agency, for the organization and mobilization of sanitary engineers, water works operators, and related man power for service in local, regional, or national emergencies.
- c. Promote civilian defense and disaster-relief planning, involving sanitary engineering and environmental sanitation, through the chief sanitary engineers of the state departments of health.
- d. Develop a system of liaison and intelligence whereby in the location, design, construction, and operation of public facilities the interests of national security are taken into adequate consideration.
- e. Alert state and local agencies of such national defense programs as are likely to affect community resources or facilities for which they are responsible.
- f. Develop training programs in environmental sanitation for professional and sub-professional people in order to establish a reservoir of trained personnel for service in times of disorder.

Abel Wolman is chairman of the Committee on Sanitary Engineering and Environment. The Subcommittee on Sanitary Engineering Aspects of Major Catastrophes is composed of Arthur E. Gorman, Chairman, Gerald E. Arnold, Anselmo F. Dappert, Victor M. Ehlers, H. H. Gerstein.

The full report appears in the June, 1948, issue of the *Journal of the New England Water Works Association*, George C. Houser, Editor, Boston 8, Mass.

SCHOOLS OF PUBLIC HEALTH ACCREDITED FOR THE M.P.H. AND Dr.P.H. DEGREES FOR 1948-1949

On April 30, 1948, the Executive Board of the American Public Health Association received the recommendation of the Committee on Professional

Education to accredit ten schools of public health for the Master of Public Health Degree (M.P.H. in the United States; the equivalent degree in Canada

is the Diploma of Public Health or D.P.H.). The Committee on Professional Education also had recommended accreditation of seven schools for the Doctor of Public Health Degree (Dr.P.H.) for the academic year 1948-1949.

The Executive Board voted to accredit these schools all of which had been accredited previously. A reduction of the number of accredited schools

from eleven in 1947-1948 to ten in 1948-1949, is due to a withdrawal of Vanderbilt University which, because of economic circumstances, is forced to discontinue the postgraduate public health training program for the present.

Below are listed the schools accredited for 1948-1949, the degrees for which they are accredited, and the names of the directors or deans.

Institutions Accredited by the American Public Health Association
To Give the Degree of Master of Public Health (Diploma of
Public Health in Canada) and Doctor of Public Health for the
Academic Year 1948-1949

NEW YORK PLANS NEW PUBLICATIONS

With the advent of Herman Hilleboe, M.D., as Health Commissioner, and Granville W. Larimore, M.D., as Director of Public Health Education, the New York State Health Department has taken a look at its weekly *Health News* and come up with plans for a weekly, a monthly, and a quarterly.

Beginning in June, *Health News* becomes a monthly publication, beamed primarily to professional health workers, and applying the principles of community organization. Its first developmental issue of April gave news about the State Medical Society and a number of voluntary health agencies, as well as an article on local health services. It was liberally illustrated with pictures, which is a part of the plan, and produced with a high grade of paper and typography. A wide distribution is planned for this publication.

The weekly publication will be the *Bulletin*, reproduced by multilith, and will have "house-organ" type of material and current communicable disease and other information of interest to public health workers. It started publication in June. The *Quarterly* will be devoted to scientific articles. Both the *Bulletin* and the *Quarterly* will be distributed to professional public health workers only.

WHAT DOES A HEALTH DEPARTMENT DO?

Perhaps a new way of answering this question has been found by the Lawrence County (Illinois) Medical Society. In a folded flier it lists each staff member of the Lawrence-Wabash bi-county health department and reproduces the exact record of what each did during one day.

The health officer of this bi-county

unit serving a population of about 35,000 is Dale E. Scholz, M.D.

THE SAFETY WORLD GETS TOGETHER

In February, 1948, the National Conference on Home Safety, originally organized in January, 1946, was dissolved. At the same time its successor, the Home Safety Conference of the National Safety Conference was born and will assume some of the aims and activities of the former organization. Among the notable achievements of the Conference during the two years of its existence was the publication and wide distribution of "A Man's Castle," an excellent home safety health education tool.

Donald B. Armstrong, M.D., who was Chairman of the Executive Committee of the earlier conference is temporary chairman of the new conference, and chairman of its Steering Committee. The next meeting of the conference will be held in connection with the 36th National Safety Congress in Chicago, October 18-22.

"IT'S IN THE BAG" A NEW FILM

The Texas State Health Department has recently released "It's In the Bag," a motion picture describing the nursing bag technique and an accompanying script. It is intended to arouse interest in high school girls in the public health nursing professions, as an aid in nursing training, as a means of getting certain health information to the public, and acquainting lay and professional groups with public health nursing service.

Details available from Texas State Health Department, Austin 2, Tex.

WORLD HEALTH ORGANIZATION UP TO DATE

The March issue of *International*

Conciliation (Carnegie Endowment for International Peace, 405 West 117 St., New York 17) is devoted to an article on the Program and Accomplishments of the World Health Organization by Professor C.-E. A. Winslow, with an introduction by Brock Chisholm, M.D., Executive Secretary of the Interim Commission, World Health Organization. Professor Winslow's article is a down to earth summary of the various areas in which WHO operates and the machinery which it employs, but in summarizing he makes the reader see also the wide horizons. This should be in the working library of every public health worker and particularly should it be read by the members of the House Rules Committee, that Committee which on March 12 tabled the resolution for United States ratification of the WHO constitution.

INDIANA MEANS IT

The February issue of the *Monthly Bulletin of the Indiana State Board of Health* is devoted primarily to promoting full-time local health services in Indiana. Its opening article on this subject is illustrated with a cartoon of racers entitled "Come On Indiana," and informs its readers that only 5 states ran behind Indiana in the race for complete state coverage with full-time health departments. There are articles by the executives of the Indiana Tuberculosis Association and the Indiana Congress of Parents and Teachers, and excerpts from the paper by George J. Nelbach of the New York State Committee on Tuberculosis and Health given at the Princeton Conference on Local Health Units. Ten counties are listed as the most likely candidates for supporting full-time service. If they should move over, in fact, from candidates to elected status, 50 per cent of Indiana's population would be covered by full-time local health service.

SCHOOL HEALTH IS GOING PLACES IN WISCONSIN

About 3 years ago in Wisconsin a committee became interested in school health services in that state. Under the sponsorship of the departments of health and education a Wisconsin Co-operative School Health Program with the aim of "better health for every child in the state" was set up.

The program has now prepared a series of 10 *Guides for Better School Health*. No. 1 is *The Road to School Health* (see January *Journal*, p. 119), and No. 10 is *Nutrition Education for Boys and Girls*. In between are pamphlets on school water supply, heating and ventilation, lighting maintenance, dental health, tuberculosis health education, school health examinations, health and safety instruction, and nutrition education. All of these bulletins are available on request from the State Department of Public Instruction, Madison.

The program has been under the direction of Warren H. Southworth, Associate Professor of Education of the University of Wisconsin. Many persons and many agencies have cooperated; 5 of the bulletins were published by the State Department of Instruction, 2 of them with funds supplied by the W. K. Kellogg Foundation; 2 by the State Board of Health, and 1 each by the Department of Agriculture and the Wisconsin Anti-tuberculosis Society.

This coöperative program has also had an annual school health conference. The report of the third one, held in October, 1947, is now also available.

MENTAL HEALTH ON THE RADIO

An exciting new series of 13 transcribed dramas on mental health, *The Tenth Man*, was recently released by the National Mental Health Foundation and is now available for sponsorship on local radio outlets or for other educational uses. Designed as tools for local mental

health societies, doctors, social workers, and others who wish to inform the public about psychiatric facts, these 15-minute radio plays dramatize some of the problems of the one man in 10 who needs or will need professional care for a mental or nervous disorder. The series has received commendation and endorsement from the Group for the Advancement of Psychiatry and the United States Public Health Service. Ralph Bellamy, noted actor, appears as narrator throughout the series, and prominent radio actors play supporting roles. For further information write to the National Mental Health Foundation, 1520 Race Street, Philadelphia 2, Pa.

THE IDEA WAS GOOD ANYWAY

The Lorain County (Ohio) Health Department held its 28th annual meeting on March 1. It celebrated, among other things, a \$35,000 two year grant from the W. K. Kellogg Foundation to establish a rural field training center for public health personnel.

Worthy of special mention, however, is its attempt to use the occasion to publicize rural health service over a wide area. It invited *Life Magazine* "to go to an annual meeting of a rural health department" giving as background material some of the facts from *Local Health Units for the Nation*, as well as some indication of the critical personnel shortage.

That *Life* did not accept the invitation, makes it no less good an idea. It takes more than one try to land in big time popular magazines.

MAYORS KNOW THE COST OF SLUMS

The United States Conference of Mayors publishes *America Cannot Afford Slums*, a graphic story in pictures and charts of the increasing financial burden and growing social problem of slums. It is designed as an argument for the Taft-Ellendorf-Wagner housing

bill. This telling argument for the bill is attractively packaged in a well printed, well illustrated booklet in pleasing colors.

HOUSES ARE HOMES

The Woman's Foundation has just published *Houses for Family Living*, a summary of the ideas discussed at the Rye, N. Y., Conference on Housing for Family Living in November, 1946. The stated purpose of the pamphlet is "an attempt to put between two covers some of the information recently acquired on family living and the home and to think through what it means." This excellent technical production is available from the Woman's Foundation, Inc., 10 East 40 Street, New York 16, N. Y., 35 cents—less in quantity orders.

It will be remembered that the Woman's Foundation initiated the chain of events that culminated in the National Conference on Family Life held in Washington, D. C., in May, 1948.

STREAM POLLUTION ABATEMENT

The *Annual Report—Interstate Sanitation Commission* for 1947 gives a record of the accomplishments of the tri-state body organized by New York, New Jersey, and Connecticut to control pollution of the greater New York bay area. Willing cooperation on the part of industry and municipalities is reported, although recourse to the legal powers of the Commission was resorted to 13 times in 1947 through issuance of orders on uncoöperative municipalities or industries. An increase in time spent in meeting requests for special services is noted as a result of continued public education. Among special activities followed was a continued participation in studies of the prevalence of marine borers, studies of storm water infiltration and storm-flow by-passing at sewage treatment plants. Results of chemical and bacteriological tests of samples taken from the various sewage

contributors in the area are presented for the years 1945, 1946, and 1947.

INTRODUCING THE TUBERCULOSIS HOSPITAL

Among the problems of a tuberculosis control program is the natural reluctance of the sufferer's family to hospitalize him away from the home and the nameless fear of hospitals that still remains in many areas. With this in mind the New York State Committee on Tuberculosis and Public Health has published, in an attractive illustrated booklet, *Your Sunmount*, subtitled, "Veterans Administration Hospital and How It Serves You."

The booklet is written for the patient and his family and describes the facilities for his cure and rehabilitation. In the process a good deal of tuberculosis health education is included. This description of a veterans' hospital in New York State to increase effective hospitalization of tuberculous veterans might well be copied elsewhere.

NLNE LEAGUE LETTER

Under date of March 5, the first *League Letter* of the National League of Nursing Education appeared. This is one of a series planned by the NLNE Committee of Public Relations to bring "brief, prompt, accurate information to state and local leagues about happenings in nursing education." Available from NLNE, 1790 Broadway, New York 19, N. Y., at 10 centes each.

A closely related publication is the *News Letter* of the Committee on the Structure of National Nursing Organizations, Volume 1, No. 1, which was issued in March. It is to be "published occasionally" and addressed to every member of the 6 national nursing organizations represented on the Committee on Structure numbering over 200,000. Available without charge from Room 201, 1790 Broadway, New York 19, N. Y.

TELLING DOCTORS ABOUT THE NATIONAL HEALTH COUNCIL

The *New England Journal of Medicine* for January 15, 1948, editorializes on the subject of Voluntary Health Agencies and the National Health Council. This outlines the services the National Health Council can give to existing health agencies. It suggests also that the American Medical Association again become a member of the Council.

The editorial is particularly valuable in interpreting for physicians and local medical societies the Council and its activities in developing local health councils. It has been reprinted by and is available in limited quantities from The National Health Council, 1790 Broadway, New York 19.

ANNUAL REPORTS

Twentieth Anniversary Annual Report, Georgia Warm Springs Foundation, is worth a few minutes for many reasons: to remind us of the physical courage and tenacity of the late President, for the information about the Foundation it contains, especially as to its growth in 20 years, and finally for the technical excellence of the pamphlet itself.

A Summary Report, Food Supply Division, The Institute of Inter-American Affairs, 1942-1947. If you want to know some of the long range attacks on bad health in Central and South America by way of soil conservation, better milk production, use of fertilizer, varied garden crops, leaf through this attractive report with its pictures.

Annual Report of the Social Science Research Council, 1946-1947, is the story of one organization's contribution to the knowledge of human relation through research. It deems its first task in research to be planning, that is, "the entire process of developing research personnel, improving techniques, mapping opportunities and needs, designing

projects, assuring the existence of proper materials, encouraging the investment of funds in research, and better the circumstances under which research is conducted."

Donald Young was the Director of the National Research Council during the period of this report. He is now General Director of the Russell Sage Foundation. His successor at the National Research Council is Pendleton Herring, formerly of the Carnegie Corporation of America and Professor of Government at Harvard University.

The offices of the Council are at 230 Park Avenue, New York 17.

WORTH ACQUIRING

Born Thirty Days Too Soon! was prepared by the Maternal and Child Health Division of the Kansas State Board of Health (Topeka) on behalf of the premature baby because he is too tiny to plead his own case. This tells the simple facts about prematurity, the facilities available, and a plea for tax money of eight cents per capita to expand the program, as well as suggestions for setting up a community program. It gives a page of pictures of great men who were premature babies—Winston Churchill, Darwin, Voltaire, and others.

Good News About Diabetes is number 138 in the series of Public Affairs Pamphlets and explains that the life expectancy of the diabetic is constantly increasing if he pays more attention to his health than the average non-diabetic. The author, Herbert Yahraes, also reports on the activities of the American Diabetes Association and the Diabetes Section of the U. S. Public Health Service, and urges increased funds for research, particularly into the why of diabetes. Public Affairs Committee, 22 East 38 St., New York 16, N. Y., Room 204.

The Unexpected Gift is one of a series of science readers for junior high school. This one, in story form, tells about a well balanced diet and how a school lunch program may be developed. Project in Applied Economics, College of Education, University of Florida, Gainesville, 35 cents, or 28 cents in orders of 25 or more.

The Problem of Cerebral Palsy by Meyer A. Perlstein, M.D., with the assistance of William McPeak, social science analyst, has been published by the National Society for Crippled Children and Adults. It is designed as "an aid to the medical profession, for leaders in community organizations, and as a guide to workers in the fields of health and rehabilitation." Included is a description of the problem of the cerebral palsied child, a suggested state program, professional training, research needs, and cerebral palsy as a socio-economic problem. There is a diagrammatic chart of how a model cerebral palsy program operates, and some hypothetical case histories illustrating the mechanics of the cerebral palsy program.

Available from the National Society for Crippled Children and Adults, Inc., 11 S. La Salle Street, Chicago 3, 25 cents.

State Administration of School Health, Physical Education and Recreation is a status study by the U. S. Office of Education. It gives the current legal and administrative provisions in the various states for the development of school programs of health, physical education and recreation. One section is devoted to coöperative arrangements between state departments of health and education.

Available from U. S. Government Printing Office, Washington 25, D. C., 15 cents.

Public Health in Foreign Periodicals

GEORGE ROSEN, M.D., PH.D.

DURING World War II, it was realized that a complete and accurate study of the influence of the war and of war conditions on public health would not become possible until the end of hostilities.¹ When the fighting ceased, public health workers in various countries began to survey the situation. Attention was turned to the problems of infant mortality, tuberculosis, venereal disease, and nutrition, that is, those problems that were found to be most pressing. So far, information has become available only in piecemeal form, relating to individual countries or to specific restricted problems. At the same time, new problems have not been neglected. In illustration of these comments, a number of investigations dealing with European countries have been selected for review.²

INFANT MORTALITY IN FRANCE

In France, the natural decrease of population already existing prior to the war was accelerated during the war years. French authors are, therefore, inquiring into the problem of infant mortality. Lesné and Debré point out that infant mortality, which had steadily declined during the years preceding the war, in 1940 showed an abrupt and considerable rise. From a rate of 110 per 1,000 live births in 1914, infant mortality had fallen to 64 in 1939. As a result, however, of conditions arising from the war and the occupation, e.g., the exodus in the summer of 1940, food difficulties, and infections, infant mortality rose to 91 in 1940, dropped to 77 in 1944, and reached 102 in 1945. It should be recalled that this was the severe winter of 1944-1945 when there

was great scarcity of food and fuel. In 1946, however, throughout France there was a sharp drop in infant mortality. The rate for France as a whole was 70 per 1,000 live births.

The authors state that about 100,000 infants under 1 year of age die annually in France. The highest infant death rate occurs before the age of 3 months; and approximately one-third of all deaths under 1 year fall under the heading of neonatal mortality. These deaths are due to various pathological conditions, and to biological, social, and economic causes. Lesné and Debré are more concerned about the latter, for it is their contention that attention to the social and economic problems could save for France three-quarters of the infants who die before the age of 1 year.

The problem of breastfeeding is considered at length. Intensification of the campaign for breastfeeding is advocated. This involves education of doctors and midwives, as well as the general public in the value of breastfeeding. Economic assistance and extra rations should be provided for every nursing mother obliged to work. Breast-milk depots should be established in every large town. Ignorance, carelessness, and poor home conditions contribute to a high infant mortality. Alleviation of these conditions requires a combination of the efforts of doctors and social workers, and an improvement in economic conditions. Furthermore, families with young children should have a priority of fuel. Finally, the authors emphasize the necessity for periodic medical supervision during pregnancy, and during the first year of life. Prenatal clinics and infant

consultation centers must constantly carry on a campaign of education with mothers.

MORTALITY AND MORBIDITY IN DENMARK DURING RECENT YEARS

A survey of public health conditions in Denmark during 1946 presents an interesting comparison with conditions preceding and during the war.⁴ The general mortality rates recorded in Denmark are lower than those observed before the war. The years 1942 and 1943 were record years, with the mortality rate dropping to a low of 9.6 per 1,000 population. Tuberculosis mortality is a sensitive index of prevailing social and economic conditions, especially the factors of nutrition and work. War, influencing as it does both of these factors, might be expected to result in a significant increase in tuberculosis mortality. Such was not the case in Denmark. The pre-war downward trend of tuberculosis mortality was checked at first, but was later stabilized. At present, the trend is again downward. During the period 1936-1940, the tuberculosis mortality rate was 40 per 100,000, whereas in the period 1941-1945, it dropped to 34 per 100,000. In 1945, the tuberculosis mortality rate was the lowest yet recorded. It is reported that deaths from all forms of tuberculosis, both pulmonary and other, were even less numerous in 1946 than in 1945.

On the other hand, the war exerted an unfavorable influence on the incidence of typhus fever, typhoid fever, dysentery, scabies, syphilis and gonorrhea. The incidence of scabies achieved a record peak in 1945. Venereal diseases spread considerably after the beginning of the war. Syphilis is reported to have been eight times more frequent in 1944 than in 1940. The number of cases of syphilis reported for these two years was 4,053 and 485 respectively. The trend with respect to gonorrhea was similar. From 1940 to 1944 the incidence of

the disease is reported to have increased threefold. The peak incidence for gonorrhea was reached in 1945. During the war there was also a rise in the mortality rate from heart disease.

BCG VACCINATION IN SWEDEN AND RUSSIA

Among the problems remaining in the wake of the war, tuberculosis occupies a prominent place. In dealing with this problem many countries are today using BCG vaccination.

The use of the Calmette vaccine in Sweden dates back to 1925 when the first trials were carried out by the oral route.⁵ Intradermal introduction of the BCG vaccine was first employed in 1927 at a children's hospital in Gothenburg, and has since been the preferred mode of administration. During the succeeding two decades the number of persons vaccinated has increased progressively. By the beginning of 1947, 500,000 persons had been vaccinated at least once. The progress of this movement has been promoted by the coöperation of governmental organizations and voluntary agencies. The Swedish National Association Against Tuberculosis has played a leading role in these developments.

Russia, too, has made extensive use of BCG.⁶ The Soviet Union was one of the first countries to undertake the study of the Calmette vaccine. In 1924, Tarashevich at Kiev received a culture from Calmette's laboratory at Paris. Belonovsky at Leningrad received a second one in 1926. After a period of preliminary studies, the first vaccinations were carried out in 1926 in the Ukraine. In 1928, vaccination was started in Leningrad, and a year later, the operation was extended to cover five large cities (Leningrad, Moscow, Saratov, Kazan, and Rostov on the Don). It was not until 1937, however, that a widespread movement was started. This movement continued even during the war. By 1940, more than two million

infants had been vaccinated. In the majority of cases the oral route has been used for vaccination. A small number of infants have been vaccinated subcutaneously.

HEMORRHAGIC FEVER IN THE CRIMEA

The Russians have also been active in the field of medical parasitology.⁷ In the spring and summer of 1944 and 1945, a mysterious hemorrhagic fever prevailed, often with fatal results among farmers and peasants in the Crimea. Investigation by a group of scientists showed that this disease was caused by a virus transmitted by the tick, *Hyalomma marginatum* Koch.

Grobov studied the local fauna in order to establish possible reservoirs of infection. After investigating various rodents, he found that only hares (*Lepus europaeus transsylvanicus*) harbor the larvae and nymphs in large numbers.

When the nymphs mature in the spring, they bite cattle and human beings, in this way transmitting the disease. The author suggests that birds may also play a role in the transmission of this fever, since nymphs of *H. marginatum* were found on several avian species.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Applied Medical Bacteriology—
By Max S. Marshall, with the collaboration of Janet B. Gunnison, Alfred S. Lazarus, Elizabeth Morrison, and Marian C. Shevky. Philadelphia: Lea and Febiger, 1947. 340 pp. Price, \$4.50.

It is a pleasure to review a book whose title so aptly describes its contents. The authors have succeeded in presenting an amazing amount of information in 340 pages, in a clear, concise, and well organized manner. The method of approach conveys the practical aspects of medical bacteriology as applied to and used by clinicians, public health workers, laboratory workers, nurses, and teachers. An attempt is made to present medical bacteriology in such a way that it will be more understandable to those who come in contact with its many ramifications.

A unique feature of the book is the 160 pages devoted to a discussion of diseases from the viewpoint of etiology, epidemiology, type of specimen for examination, laboratory procedures, and methods of reporting. Excellent judgment is shown in the choice of laboratory procedures, which are clear and up-to-date.

Other chapters deal with specific procedures, such as cultivation, isolation, general techniques as used in bacteriology, the use of laboratory animals and culture media, and general information regarding virology and mycology. An excellent chapter on the collection of specimens and the principles involved adds materially to the value of the book for clinicians and laboratory workers.

The appendix is exceptionally well treated, with clear tables regarding diseases, causative agents, specimens for

examination, pertinent animal and serologic tests, stains, reagents, and diagnostic antigens and antisera.

This well organized text, with its abundance of factual information, should be available in every laboratory doing bacteriologic and serologic diagnostic tests. MELVIN E. KOONS

The Pathology of Nutritional Disease—By Richard H. Follis, Jr., M.D. Springfield, Ill.: Thomas, 1948. 291 pp. Price, \$6.75.

This book fills a real need and both Dr. Follis and the publisher are to be congratulated, the former for getting together in one place the pertinent pathology involved in many nutritional deficiencies, and the latter for doing a good job of printing and reproduction of the pathology plates. The best sections of the book deal with the author's own work on the pathology of scurvy and rickets. The subtitle of the book is "Physiological and morphological changes which result from deficiencies of the essential elements, amino acids, vitamins, and fatty acids." In general, the sections dealing with physiological changes are so brief that one might question whether they should even have been included, but certainly not in the subtitle. The book is well written and reads easily. The author's frequent use of the phrase "of course"—"such changes are, of course, partially explained by the deranged calcium and phosphorous metabolism . . .—arginine is probably one of the precursors of creatine and, of course, acts as a catalyst in the synthesis of urea . . ." tends to over simplify many statements. Everyone in the field of experimental nutrition will enjoy and

thank Dr. Follis for his splendid contribution.

FREDERICK J. STARE

Hearing and Deafness—A Guide for Laymen—*Edited by Hallowell Davis, M.D. New York and Toronto: Murray Hill Books, Inc., 1947. 496 pp. Price, \$5.00.*

According to the Editor, "This book is written for the deaf and the hard of hearing and for their families, their parents, their teachers and their friends. It is written for physicians, for educators, for social workers, and for all who are concerned with the conservation or improvement of remaining hearing; or with the approach to normal living for those who have suffered either complete or partial hearing loss." Dr. Davis and his thirteen contributors have written an admirable book which should be on the shelves of public health workers whose programs include, or should include, programs of hearing conservation.

Certain sections are too difficult for some readers; however, they are clearly posted in advance so they may be omitted if the reader wishes. For the most part the book is easy to understand. It is interesting and scientifically sound.

Public health workers will find the chapter on testing for hearing especially useful. That on the psychology of the hard of hearing and deaf is illuminating. The chapter on hearing aids has many practical tips for the user of aids. The reader cannot fail to be impressed by the many professional skills, including speech reading, auditory training and vocational guidance that must be utilized to meet the needs of patients adequately, and by the large number of hard of hearing and deaf people in the United States.

The public health administrator will be interested in the chapter on the military program of aural rehabilitation. By analogy he can learn of the organization of services required for many civilian needs. Although organizations for

the aurally handicapped are discussed, the administrator will look in vain for a complete discussion of the efforts made in the United States to develop Conservation of Hearing Programs as part of community health programs. An additional chapter summarizing programs such as those stimulated by the Children's Bureau would have made this fine book even better—at least for the health administrator, for whom it was not primarily written.

WILLIAM R. WILLARD

Communicable Disease Control—*By Gaylord W. Anderson, M.D., and Margaret G. Arnstein, R.N. (2nd ed.). New York: Macmillan, 1948. 450 pp. Price, \$5.00.*

The seven years that have elapsed since the publication of the first edition of this excellent work on public health have witnessed many important changes in communicable disease control, most of which have been included in this new edition. New antibiotics, sulfonamides, and antigens have come into common use for the prevention and control of many infections, and their application to preventive medicine has been capably described.

As in the previous edition, the first part of the book deals with the control of the communicable diseases in general; the second with the prevention and treatment of particular diseases. A chapter on rheumatic fever has been added. On the whole, an excellent textbook on preventive medicine has been achieved and only a few minor criticisms can be made.

On page xiii the list of tables spread through the text fails to give the page numbers where the tables can be found. Incubation periods mentioned are not all in entire agreement with those usually found in medical texts. For instance, that of mumps is given as 3 weeks instead of the more usually stated 16 to 18 days. In the bibliographies,

although this is a 1948 book, there are very few references to articles appearing in 1947; and for the chapter on poliomyelitis, a subject on which there has been a great deal written in the last two years, there is no 1947 reference and only one for 1946.

This book can be very warmly recommended to doctors and nurses working in the public health field, and pediatricians interested in preventive medicine will also find much of interest and value in a study of this text.

PHILIP M. STIMSON

Public Health Administration in the United States—*By Wilson G. Smillie. (3rd ed.) New York: Macmillan, 1947. 637 pp. Price, \$6.50.*

This third edition, published seven years after the second, is divided into four parts.

The first presents an analytical and historical development of the public health movement. The functions of public health are listed by Smillie as Sanitation, Control of Communicable Diseases, Public Health Education, Individual Health Protection, and the Development of a Nation-Wide Program of Adequate Comprehensive Medical Care.

Part two summarizes the many scientific and administrative developments in the control of communicable diseases: particularly streptococcal infections, as a group of diseases; tuberculosis with case finding rules and mass surveys; malaria and chemotherapy; meningococcus meningitis and sulfonamide prophylaxis. Critical evaluation of community immunization procedure is an important contribution. The numerous charts, maps, diagrams, and an extensive bibliography add to the value of the text.

Part three contains a chapter on each of eleven basic activities of a health department. The child health chapter covers the entire gamut of services from maternal hygiene and the EMIC pro-

gram through school health, with emphasis on dental hygiene.

Part four is the most outstanding of the book. For the student or teacher of public health practice it is a good summary of the federal agencies and the types of administration existing in the states, municipal, and rural areas. It includes a discussion of voluntary agencies and disaster relief. Final chapters span administrative problems from public relations with the medical profession to budgets and personnel training.

An appendix contains personnel qualifications for some of the key positions of the health department.

The text reflects the experiences brought to public health from World War II. It is an excellent text for students of public health, particularly those without experience or a medical background. It is a reference book which each health department should make available to its personnel.

VLADO A. GETTING

A Synopsis of Hygiene—*By G. S. Parkinson, D.P.H., assisted by Kathleen M. Shaw, M.B.E. (9th ed.) London: J. and A. Churchill Ltd., 1947. 791 pp. Price, \$8.25.*

The Jameson and Parkinson textbook on hygiene has been revised faithfully since the first edition appeared in 1920. This ninth edition is the first to indicate the influence on public health practice of the Education Act of 1944, the National Health Service Act and the National Insurance Act of 1946. Further modifications in the text result from changes in British hospitalization policies and from changes in the requirements for the Diploma of Public Health. The reader of this edition is constantly impressed with the impact of social legislation and increasing authority of the Ministry of Health upon British public health.

The material in this book is a veritable treasury of technical information

on public health and preventive medicine. Organization of material differs considerably from that found in American textbooks. The epidemiologist will find no particular order of presentation of disease control; the industrial hygienist will have to browse through at least four of the nine sections; there is little help for those who are interested in the public health laboratory or in nursing. But public health and hospital administrators, engineers, nutritionists, maternal and child hygienists, and those interested in public health law will find this volume constantly useful as a reference guide. CHARLES E. SHEPARD

A Manual of Medical Parasitology, with Techniques for Laboratory Diagnosis and Notes on Related Animal Parasites—By C. Courson Zelif, M.S., Ph.D. State College: Pennsylvania State College, 1947. 159 pp. Price, \$3.75.

This is a paper-bound, lithoprinted volume of typewritten notes, tables, and keys, describing the appearance and morphology of parasites—principally of man—and laboratory methods, direct and indirect, of recognizing various types of parasitic infection. The symptomatology, treatment, and prevention of parasitic disease are scarcely mentioned. A classification of human parasites by phylum, class, order, family, genus, and species is included, and special sections deal with medical protozoology, helminthology, arachnology, and entomology. These are illustrated by some 68 figures on 13 plates. None of these are original with the author and many of them are so reduced in size and poorly reproduced as to be worthless; in many instances the captions cannot be read without a reading glass. Numerous tables of differential characteristics and keys for the separation and identification of related forms are presented; the majority of these are reprinted from well known texts on parasitology. The typescript

was poorly proof-read and abounds in errors of punctuation, spelling, grammar, and diction. The compilation of notes on laboratory techniques is useful, as it includes very recent observations and developments in this field, but these are not treated critically. References are given throughout the text, in footnotes and at the end of the volume.

JUSTIN M. ANDREWS

American Medical Research, Past and Present—By Richard H. Shryock, Ph.D., New York: The Commonwealth Fund, 1947. 350 pp. Price, \$2.50.

This monograph, one of the studies prepared under the auspices of the Committee on Medicine and the Changing Order of the New York Academy of Medicine, is a very worthy addition to that series. Dr. Shryock presents an account of the development of American medical research from the middle of the 18th century to the present. Particular emphasis is placed on the developments of the past half century and on their relevance for the present state of medical research.

Beginning with the formative influences that shaped American medical research—British, 1750–1820; French, 1820–1860; German 1860–1895—the author traces the factors that led, around the turn of the century, to the emergence of American medicine on “a level of cultural independence.” The multifarious elements that enter into the activity known as research are dealt with judiciously and in proper perspective. Dr. Shryock examines the rôles of institutions (Johns Hopkins Medical School) and of persons (William H. Welch), and appraises the significance of private support and the rise of the great philanthropic foundations for the maturation and growth of medical research.

Within the brief compass of this volume, the author examines such important questions as the relation of research to teaching, academic salaries,

medical publications, trends in medicine, and the impact of the changing social and economic background on private and public agencies in supporting research. Finally, he points out that mere technical advance is not enough. What is needed in addition is an appreciation of the cultural significance of science itself. This can be obtained by means of historical perspective. Toward this end Dr. Shryock's volume is a solid contribution. GEORGE ROSEN

Health Instruction Yearbook, 1947
—*Edited by Oliver E. Byrd, M.D.*
Stanford, Calif.: Stanford University Press, 1947. 325 pp. Price, \$3.00.

The 1947 edition of the *Health Instruction Yearbook* will take its place as a welcome companion volume to the *Yearbooks* of preceding years. Because of the increasingly rapid flow of experience in medicine, public health, and allied fields, there is great need for a volume such as this which records in a most convenient form summaries of recent health developments.

As in previous editions of the *Yearbook*, the editor has cast his net wide and has secured information on subjects ranging from the vitamin content of mushrooms to the details of the charter of the World Health Organization. Very little of importance on the health scene of 1947 has been omitted. One feels, however, that certain items might have been deleted. For instance, there seems little reason for the entry about a former postmaster general and his high blood pressure. Nevertheless, this item is indicative of the miscellany of health information to be found in the *Yearbook's* pages.

The editorial labor involved in compiling a book of this sort is exemplified by the editor's prefatory statement in which he says that 1,672 articles and news sources were reviewed. Of this number 323 were culled for inclusion in the 1947 edition. Thus, one can be as-

sured that the text touches on practically every aspect of health that excites interest today. Moreover, the editor's introductory comment to each chapter are as interesting and useful as the factual items treated.

The book is highly commended. As a ready reference source, it is admirably compiled and organized. Every public health library should possess this volume for the *Yearbook* is not only a notable undertaking but an unmixed blessing to those who want to keep abreast of progress in the profession.

JOHN LENTZ

Opiate Addiction—By Alfred R. Lindesmith. *Bloomington, Ind.: Principia Press, 1947. 235 pp. Price, \$3.00.*

In this volume, Professor Lindesmith "... aimed to develop ... an interpretation that would ... cover all instances of drug addiction." His understanding of the physiological and emotional mechanisms of drug addiction is meager, his arguments specious and his proposed "reforms" dangerous to the public health. The book and other writings of Professor Lindesmith represent arm-chair philosophical rumination on material obtained from "sixty to seventy" addicts about fifteen years ago. He declined, as unnecessary, an opportunity to study several hundreds of addicts before writing the book.

The author's thesis is that habitual users of narcotic drugs do not become addicts until after they have experienced withdrawal distress, known its nature, experienced relief of withdrawal symptoms by readministration of the drug, and have learned the name of the drug. This explanation will not satisfy most students of drug addiction. In the first place, it does not explain why the habitual user or "future addict" takes the drug often and regularly enough to become physically dependent on it, nor does it explain animal addiction. In the

second place, Professor Lindesmith does not understand that addiction and read-diction depend upon personality characteristics and emotional needs; he does not recognize the "addiction-prone" individual repeatedly described by Kolb and others. Most readers will be astonished at the naivete with which the author, without knowledge or regard for psychiatric concepts, has the temerity to discuss dynamics of drug addiction.

In spite of known weaknesses of "police" control of narcotic addiction in the United States, which the author proposes to abolish, the fact remains that since the Narcotic Act was passed in 1915 there has been a substantial decline in the number of addicts in this country, although the author leaves one in doubt as to whether he believes a decrease in drug addiction is really desirable.

Professor Lindesmith approves federal hospitals for treatment of drug addiction for those who wish to go voluntarily, but fails to realize, or thinks it immaterial, that only a very few would choose treatment if drugs were freely available on prescription, as he recommends. He believes the common rationalization of addicts, that drugs make them more efficient. The truth is that addicts who have the quantity of drug they desire become inefficient, lazy, somnolent, and careless of person. Professor Lindesmith mentions as an advantage of this free prescription that contraband drug traffic would be wiped out, and the addicts would be able to get their required drugs at a reasonable price, as if that were desirable. Public clinics and free prescription of drugs for addicts have been tried several times with disastrous results; addicts deceive the physicians and get extra drugs which they peddle in contraband channels, or give to their friends, who then become eligible for dispensation of drugs and a

vicious spread of addiction is thus established.

Proposal for unrestricted prescription of narcotics for addicts is naïve in the extreme and dangerous to the public health of the nation. Fortunately, sounder judgment than the author's will prevail and there is no likelihood of the "reforms" which he proposes being carried out.

VICTOR H. VOGEL

Symposium on Medicolegal Problems. Under the Co-sponsorship of the Institute of Medicine of Chicago and the Chicago Bar Association—*Edited by Samuel A. Levinson, M.D., Ph.D. Philadelphia: Lippincott, 1948. 255 pp. Price, \$5.00.*

On those rare occasions when doctors and lawyers get together to discuss mutual problems both groups invariably learn something. At six notable meetings of this sort the members of these two professions in Chicago gathered to listen to papers and to ask questions about: (1) the medical witness; (2) artificial human insemination; (3) the practice of pathology; (4) operations for sterility; (5) trauma and cancer; and (6) blood tests for paternity and chemical tests for intoxication. These vexing problems were clarified and explained, if not exactly solved, by speakers representing the medical and legal points of view, supplemented by discussion from the floor, which is fully reported and sometimes is more brilliant than the original paper. Although based mainly on Illinois experience, the material is of general interest and value, and might well set a pattern for similar assemblies in other states or in the larger cities. This well printed book will appeal to those who are concerned with the six special medicolegal problems which are so ably discussed in it.

JAMES A. TOBEY

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

In Battle Array—What the National Cancer Institute will do with the fourteen millions entrusted to it should prove an effective antidote against despair. It's assuring just to read of the magnitude and the scope of the work, being done without fanfare, fireworks, or benefit of radio comedians.

ANON. The Program of the National Cancer Institute. *Pub. Health Rep.* 63, 16:501 (Apr. 16), 1948.

From the Experts—Though a half million syphilitics have been treated with penicillin, and though that drug is now the principal agent employed, treatment is not yet entirely standardized. This report is the last word in that direction.

ANON. The Status of Penicillin in the Treatment of Syphilis. *J.A.M.A.* 136, 13:873 (Mar. 27), 1948.

"Theirs Not to Reason Why"—Having proved himself to be an effective delinquent case chaser-upper the put-upon Western Union messenger was sent out to bring in reported venereal disease contacts. Of the 1,500 he called upon, 47 per cent reported within 3 days, a better response than health board visitors procured.

BAUER, T. J., *et al.* The Telegram as a Case-Finding Technic in Venereal Disease Control. *Ven. Dis. Inform.* 29, 2:42 (Feb.), 1948.

Human Souls, Not Cases—This is an effective plea for more and better social work in connection with the detection and care of the quarter million tuberculosis patients we have on our national hands.

BLOOM, S. Some Economic and Emotional Problems of the Tuberculosis Patient and His

Family. *Pub. Health Rep.* 63, 14:448 (Apr. 2), 1948.

One in Six Gets It—It's time we did something more about trichinosis, this distinguished committee says. It recommends excluding from New York pork from hogs fed uncooked garbage, prohibiting shipment of uncooked garbage from town, and its feeding in-town, among other measures.

CORWIN, E. H. L., and STICE, L. Control of Trichinosis (Committee Report) *Pub. Health Rep.* 63, 15:478 (Apr. 9), 1948.

Incidental Intelligence—Reported cases of polio were fewer in 1947 than any year since 1942. Epidemics occurred in only small areas. England and some of the continental countries were hard hit.

DAUER, C. C. Incidence of Poliomyelitis in 1947, (and) BRADLEY, W. H., and GALE, A. H. Poliomyelitis in England and Wales in 1947. *Pub. Health Rep.* 63, 13:393 (Mar. 26), 1948.

Science Marches On—Don't let the word "therapy" in the title persuade you that this paper is for practising physicians only. It is for every professional worker who wants to know what's back of the rule-of-thumb nutritional precepts he preaches to others, or neglects to apply to himself. Not to be missed!

ELVEHJEM, C. A. Recent Progress in Nutrition and Its Relation to Drug Therapy. *J.A.M.A.* 136, 14:915 (Apr. 3), 1948.

Canners, Take a Bow!—From a year-long nation-wide survey of canned, frozen, and fresh fruit and vegetables comes the conclusion that canned foods cost least and offered the best nutri-

tional values from an economic standpoint.

KREHL, W. A., and COWGILL, G. R. Comparative Cost and Availability of Canned, Glassed, Frozen, and Fresh Fruits and Vegetables. *J. Am. Dietet. A.* 24, 4:304 (Apr.), 1948.

They're Still at Large—Note for your book: penicillin applied locally cleared up diphtheria carriers.

LEVY, A. J. Local Treatment of Carriers of Virulent Diphtheria with Penicillin. *J.A.M.A.* 136, 13:855 (Mar. 27), 1948.

Facts About Food—Promised as the first of a series of papers on nutrition (to be published later in book form), this one is full of facts about cereals, legumes, vegetables, and fruit. I can't remember ever reading an article with more facts heaped up, pressed down, and pounded in, than this one.

MAYNARD, L. A., and NELSON, W. L. Foods of Plant Origin. *J.A.M.A.* 136, 16:1043 (Apr. 17), 1948.

As Our Population Ages—First of a series of statistical papers on heart disease morbidity and mortality, this one presents two graphs you should find useful, the percentage of population in age groups and percentage of deaths in these groups. A more dramatic presentation of the fact that our saving of lives has been in childhood and early adult ages would be difficult to conceive.

MORIYAMA, I. M., and GOVER, M. Statistical Studies of Heart Disease. *Pub. Health Rep.* 63, 17:537 (Apr. 23), 1948.

Anent Healing Thyself—How are you? Do you bite your nails, drink too much, take barbiturates? Does your anger or fit of tension persist beyond natural limits? Do you enjoy ill-health? You may still not be beyond gaining a better insight into your own condition by reading this dissertation on psychosomatic medicine, which, the writer points

out, is akin to preventive medicine in many ways.

RUESCH, J., and BOWMAN, K. M. Personality and Chronic Illness. *J.A.M.A.* 136, 13:851 (Mar. 27), 1948.

1948 Complications—Ping-pong syphilis is a new descriptive for your vocabulary. The infection is batted back and forth from the infectious partner to the one who has just completed treatment. Under penicillin therapy the situation is not rare. Ways to stop it are discussed.

SCHAMBERG, I. L., and STEIGER, H. P. Syphilitic Relapse vs. Reinfection. *Ven. Dis. Inform.* 29, 4:92 (Apr.), 1948.

State Paper—Preventive geriatrics, mental health, and research seem to be uppermost in the mind of the new Surgeon General as he takes command of the U.S.P.H.S. You'll want not to miss this address.

SCHELLE, L. A. The Road Ahead in Public Health. *Pub. Health Rep.* 63, 15:472 (Apr. 9), 1948.

You'll Be Surprised—As part of their course of training these students were required to go out and start a group along the road to better health. Some of the unusual enterprises the youngsters thought up are briefly described.

STEINHAUS, A. H. Adventures in Health Education. *J. School Health*, 18, 4:103 (Apr.), 1948.

DeLuxe Model—This is about an agreement worked out between the executive officers of the Rochester (Minn.) Public Schools and the Public Health Department, to provide complete school health services by a staff of 25 qualified physicians, nurses, and educators—for 5,000 children.

THOMAS, M. J. Unifying Health Services Through Public Education. *Pub. Health Nurs.* 40, 4:168 (Apr.), 1948.

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- ASEPTIC TREATMENT OF WOUNDS.** Carl W. Walter, A.B., M.D. New York: Macmillan, 1948. 372 pp. Price, \$9.00.
- BIOLOGY AND HUMAN AFFAIRS** (new ed.). John W. Ritchie. New York: World Book Company, 1948. 818 pp. Price, \$3.40.
- CARDIOVASCULAR SYPHILIS.** New York: Social Hygiene Committee-N. Y. Tuberculosis and Health Association, 1948. Reprinted from Vol. IV., No. 2, February, 1948. pp. 248-278. American Journal of Medicine.
- CARE AND MANAGEMENT OF LABORATORY ANIMALS.** Edited by Alstair N. Worden, M.A.B.Sc. Baltimore: Williams & Wilkins, 1947. 368 pp. Price, \$8.50.

- WEST VIRGINIA MERIT SYSTEM COUNCIL. 5th Report. January 1, 1946 to June 30, 1947. Charleston, W. Va. Office of the Supervisor. 26 pp.

cations are accepted up to August 1 each year for consideration by the Governing Council at the fall meeting. It is important to make clear that members themselves should take the initiative in submitting such applications. Neither the Sections nor the A.P.H.A. administrative staff are authorized to solicit applications. This means that, although nearly 3,000 persons have been duly recognized with this grade of affiliation since 1922, there are other persons well qualified who have never initiated the process of applying for Fellowship. It should be clear that members should not await action by others if they wish to attain Fellowship. It is necessary and proper for them to take the first step.

An application for Fellowship requires sponsorship by two Fellows of the Section with which the applicant desires to be affiliated. These personal signatures are to be obtained by the applicant before submitting the completed application. The A.P.H.A. office will assist, on request, in determining the Section with which prospective sponsors are affiliated. Applications from persons not wishing to be identified with a particular Section and requesting unaffiliated Fellowship may be sponsored by any two Fellows of the Association.

When properly sponsored and otherwise completed, the application is sent to the A.P.H.A. office, after which the list of persons applying is published in the *American Journal of Public Health*, usually in the September issue, but in any case not less than 15 days before the date for the Annual Meeting. An established routine is followed for review by the Section Councils (unaffiliated applications are reviewed by the Executive Board) and by the Commit-

tee on Eligibility. This Standing Committee of the Association is made up of one Fellow from each of the 12 Sections, plus a Chairman elected by the Executive Board. This group is under instructions from the Governing Council to examine each application in accordance with the provisions of the clause of the By-laws chosen by the applicant, and to apply the criteria with precision in each case. Final election is by the Governing Council at the second meeting at each annual session.

The privileges of Fellowship include eligibility to serve as an officer of the Association or one of the Sections, Chairman of an Association or Section Committee (over one hundred in number), a member of one of the four Standing Committees, a member of the Governing Council or Executive Board, and the right to vote at the Annual Meeting for the elective members of the Governing Council and on amendments to the Constitution. Some Civil Service and merit system records depend upon Fellowship in the American Public Health Association as an achievement deserving recognition in applicants.

The dues of Fellows are \$12.00 annually, and include a subscription to the *American Journal of Public Health* and other services to which members are eligible. Life Membership is available at \$200, covering all future annual dues.

Applications for Fellowship to be considered at the 76th Annual Meeting in Boston, Mass., November 9-12, 1948, should be filed with the Association as soon as they are completed, and in any case not later than August 1. For further information, address the Membership Department, American Public Health Association.

THE 76TH ANNUAL MEETING

Boston, Mass., November 8-12, 1948

Hotel Reservation Form

The hotels listed below have rooms available for Association delegates at the rates indicated. Please note that **NO RESERVATIONS WILL BE ACCEPTED DIRECTLY BY HOTELS.** Make your reservation through:

THE HOTEL IS NOTIFIED OF LATE ARRIVALS

APPRECIATION OF DR. CARL E. BUCK
BY THE C.A.P.

At its meeting in New York in March the Executive Committee of the Committee on Administrative Practice adopted the following resolution with respect to Dr. Carl E. Buck who resigned his position as Field Director of the Association in February to become Resident Lecturer in Public Health at the University of Michigan School of Public Health:

BE IT RESOLVED that we, the members of the Executive Committee, for ourselves and for all the members of the Committee on Administrative Practice, express herewith our deep regret that Dr. Carl E. Buck, Field Director, has found it necessary to resign from this important position after seventeen years of continuous service.

Since his appointment in 1931 he has completed surveys of 17 states, the Territory of Alaska, and the Province of Manitoba. His studies have included 36 local communities—cities and counties—and follow-up consultant and advisory visits to the number of 64 in states where studies had been made.

This formidable list of detailed inquiry and recommendation for the administration of state and local health departments does not include a multitude of services to states, cities, and counties in connection with the Evaluation Project or his participation at conferences, institutes, and national, state, and local public health meetings.

His loyalty to the professional objectives and standards of the American Public Health Association, his critical and constructive analyses of official and voluntary health services, and his persuasive and courageous expressions of sound opinion for the betterment of these, often in the face of political, popular, or press criticism, have marked his labors with high quality and consistency.

Dr. Buck's personal and professional contributions to the work he undertook have left a permanent mark upon the purpose and pattern of public health service in the United States and Canada.

The committee wishes him many years of further productive contribution to the teaching of the principles of public health administration in the friendly and coöperative atmosphere of an academic environment.

COMMITTEE ON ADMINISTRATIVE PRACTICES OF THE INDUSTRIAL HYGIENE SECTION

Omitted inadvertently from the Committee List published in the *Year Book* was the following committee of the Industrial Hygiene Section:

COMMITTEE ON ADMINISTRATIVE PRACTICES
J. G. Townsend, M.D., *Chairman*, Industrial Hygiene Division, U. S. Public Health Service, Washington 25, D. C.
W. E. Frederick, Ph.D.
J. M. MacDonald, M.D.
V. A. Nasatir, M.D.
M. F. Trice, B.S.
Miss J. Y. Ziano

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

J. R. Brandon, M.D., City Health Dept., High Point, N. C., City Health Officer
Arthur F. Chaisson, M.D., C.M., Provincial Dept. of Health, Fredericton, N. B., Canada, District Medical Health Officer
Gerald R. Clark, M.D., 411 Capitol Bldg.,

Phoenix, Ariz., Senior Asst. Surgeon, U.S.P.H.S., Director of Tuberculosis Control, State Health Dept.
Catherine E. Coleman, M.D., Clay County Health Dept., West Point, Miss., Health Officer
William E. Gregson, M.D., M.P.H., Sick Mari-

ners' Clinic, Immigration Bldg., Vancouver B. C., Canada. Quarantine Officer in Charge

Vane M. Hoge, M.D., U. S. Public Health Service, Washington, D. C., Medical Director and Chief, Division of Hospital Facilities

Philip A. Klieger, M.D., Cass Lake Indian Hospital, Cass Lake, Minn., Senior Physician, U. S. Indian Service

Adolph G. Liedloff, M.D., 222 South Front St., Mankato, Minn., Acting Director, District No. 2, State Dept. of Health

E. E. McClellan, M.D., Kaparoulis Bldg., Williamson, W. Va., Mingo County Health Officer

Ruth McDougall, M.D., D.P.H., Red River Health Unit, Ste. Anne des Chenes, Man., Canada, Medical Director

Alejandro Guevara-Rojas, M.D., M.P.H., Martires de Tacubaya 70, Mexico, D. F., Mexico, Director, Unidad de Salubridad y Estacion de Adiestramiento de Xochimilco

John W. Spies, M.D., M.P.H., State Board of Health, Marshallton, Del., Director, Divisions of Cancer Control and Communicable Diseases, State Board of Health

Leroy K. Young, M.D., U. S. Public Health Service, Manila, Philippines, Consultant on Tuberculosis to Philippine Public Health Rehabilitation Program and Chief, Tuberculosis Control Division, U.S.P.H.S.

Laboratory Section

Rena L. Dodd, 1026 New Scotland Road, Slingerlands, N. Y., Bacteriologist, State Dept. of Health

E. H. Garrard, M.S., Dept. of Bact., Ontario Agricultural College, Guelph, Ont., Canada, Professor and Head, Dept. of Bacteriology

Roderick D. Hamblin, 3086 Stoddard Ave., San Bernardino, Calif., Laboratory Director, San Bernardino County Public Health Laboratory

Dorothy Lewis, Richards Chemical Works, 190 Warren St., Jersey City 2, N. J., Research Bacteriologist and Laboratory Supervisor

Irving J. Lipovsky, M.S., Biology Dept., Univ. of Massachusetts, Fort Devens, Mass., Asso. Professor of Bacteriology

Denys R. Lock, M.A., 1709-21st St., Everett, Wash., Director of Laboratory, Providence Hospital

Frank R. Martuccio, 1422½ Barry Ave., West Los Angeles, Calif., Bacteriologist, U. S. Veterans' Center

Celia Rubin, 2839 India St., San Diego, Calif., Senior Laboratory Technician, City Public Health Laboratory

Helen R. Seraichekas, 19 Barrett St., Cranston,

R. I., Medical Technician, U. S. Veterans' Administration

Kenneth E. Shull, 762 Lancaster Ave., Bryn Mawr, Pa., Chief Chemist and Superintendent of Purification, Philadelphia Suburban Water Co.

Kenneth W. Stewart, 1217 Harrison, Kansas City, Mo., Production and Quality Control, Franklin Ice Cream Co.

Vital Statistics Section

Vira Anderson, R.N., Salem Memorial Hospital, Salem, Ore., Medical Record Librarian

Stephen S. Henkin, 555 Prospect Place, Brooklyn 16, N. Y., Chief Record Librarian, Jewish Hospital of Brooklyn

Judith Killeen, 6300 Beacon Ave., Seattle 8, Wash., Advisory Field Clerk, State Dept. of Health

Virginia M. Riley, Barre City Hospital, Barre, Vt., Chief Record Librarian

Henry S. Robinson, 23 Grove St., New York 14, N. Y., Field Statistician, American Cancer Society

Martha C. Wood, 237 Pontotoc, Houston, Miss., Business Manager and Medical Record Librarian, Houston Hospital

Engineering Section

Irwin G. Bircher, D.V.M., 50 University Ave., Rochester 5, N. Y., County Veterinarian

Harlan G. Formo, M.P.H., 115 Court House, Duluth, Minn., Public Health Engineer, District IV, State Health Dept.

Alfred A. Gannon, 16205 Tracey, Detroit 27, Mich., Sanitarian, Wayne County Health Dept.

Pharm. Ralph T. Goerner, Jr., (HC) USN, U. S. Naval Station, Treasure Island, San Francisco, Calif., Sanitarian

Eric J. Hannemann, 806 Highland Ave., Austin, Tex., Graduate Work in Sanitary Engineering, Univ. of Texas

Bernard L. Jacobson, Box 2892, University, Ala., Student, Univ. of Alabama

C. C. Potter, 3520-54th, Des Moines 10, Iowa, Asst. Sanitary Engineer, State Dept. of Health

Thomas J. Rinaldo, 465 Concord St., Framingham, Mass., Asst. Sanitary Engineer, Water Division, Metropolitan District Commission

Major Clyde M. Turner, MSC, 9839th TSU, Engineer School, Ft. Belvoir, Va., Sanitary Engineer

Industrial Hygiene Section

George G. Richards, 1940 South 16th East, Salt Lake City 5, Utah, Industrial Hygiene Technician, State Health Dept.

Food and Nutrition Section

Marian L. Arnold, 172 Westminster St., Hamden 14, Conn., Nutrition Director, Connecticut Dairy and Food Council

Slava Malec, 217 E. Broad St., Bethlehem, Pa., Staff Nutritionist, State Dept. of Health

Margaret A. Ohlson, Ph.D., Michigan State College, East Lansing, Mich., Head, Foods and Nutrition Dept.

Maternal and Child Health Section

Catherine D. Carlson, M.D., International House, Berkeley 4, Calif., Student, School of Public Health, Univ. of California

Ernest W. Hancock, M.D., 1103 State House, Lincoln, Neb., Chief, Division of Services for Crippled Children, Dept. of Assistance and Child Welfare

Pedro Magana-Erosa, M.D., 10/a. de Puebla 204, Depto. 6, Mexico, D. F., Mexico, Pediatrician, Unidad Sanitaria y Estacion de Adiestramiento de Xochimilco

Henrietta L. Marquis, M.D., Medical Arts Bldg., Charleston, W. Va., Pediatric Consultant, State Health Dept.

Ursula G. Sanders, M.D., 17 Capitol St., Concord, N. H., Asst. Director, Maternal and Child Health Division, State Dept. of Health

Jessie J. Turnbull, Sc.D., Elizabeth Steel Magee Hospital, Pittsburgh 13, Pa., Supt.

Public Health Education Section

Samuel J. Barham, 601 Topeka Blvd., Topeka, Kans., Exec. Director, Kansas Hospital Service

Francis G. Bean, M.D., 223 Washington Ave., Bennington, Vt., Administrator, Putnam Memorial Hospital

Mary I. Cawley, 364 Edison St., Staten Island 6, N. Y., Public Health Analyst, Venereal Disease Research Laboratory, U.S.P.H.S.

Louie H. Crowl, D.D.S., 3201 Cutter Way, Sacramento 17, Calif., Director of Health Education, McClellan Air Force Base

Ruth L. Flater, 526 Goodwyn Institute, Memphis, Tenn., Sec., Health Section, Community Council of Memphis-Shelby County

Arden E. Hardgrove, 231 West Oak St., Louisville 3, Ky., Administrator, Norton Memorial Infirmary

Ruskin King, M.D., 10 West Taylor St., Savannah, Ga., Private Pediatrician

Fraser D. Mooney, M.D., C.M., 100 High St., Buffalo 3, N. Y., Supt., Buffalo General Hospital

Mary H. Parks, M.P.H., 18 Dove St., Albany, N. Y., Asso. Public Health Educator, State Dept. of Health

Willard C. Rappleye, M.D., Sc.D., 630 West 168th St., New York, N. Y., Dean, Faculty of Medicine, Columbia Univ.

Lauritz S. Ylvisaker, M.D., Fidelity Mutual Life Insurance Co., 25th and Parkway, Philadelphia, Pa., Vice-President and Medical Director

Lawrence Zuccolo, 723-17th St., Union City, N. J., Student, New York Univ.

Public Health Nursing Section

Maude C. Bailey, M.A., 4217 Blossom St., Columbia, S. C., Hospital Consultant, Maternal and Child Health Division, State Board of Health

Margaret G. Bennett, c/o North American Embassy, Montevideo, Uruguay, S. A., Consultant Public Health Nurse, Institute of Inter-American Affairs

Anna K. Bergstrom, R.N., 307 Court House, Springfield, Mo., Public Health Nurse, State Crippled Children's Service

Judith S. Cantor, 500 Riverside Drive, New York, N. Y., Student, Teachers College, Columbia Univ.

Florence M. Clark, R.N., 17 Capitol, Concord, N. H., Director, Public Health Nursing Division, State Dept. of Health

Elizabeth Dills, R.N., B.S., George A. Hormel & Co., Austin, Minn., Nurse Consultant and Visiting Nurse

Amelia M. Engel, 2300 Bronx Park East, Bronx 67, N. Y., District Supervising Nurse, City Dept. of Health

Hylde A. Harp, R.N., M.P.H., 2825 N. 58th St., Milwaukee, Wis., Supervisor of School Hygiene, City Health Dept.

Lucile M. Johnson, R.N., B.S., 805 Sixth St., Eureka, Calif., Supervising Public Health Nurse, Humboldt County Dept. of Health

Genevieve S. Jones, 2405 First St., N. W., Washington, D. C., Senior Asst. Nurse Officer and Tuberculosis Nursing Consultant, U. S. P.H.S.

Marjorie A. McIntosh, Ottawa Civic Hospital, Range Rd., Ottawa, Ont., Canada, Instructor of Nurses and Asst. Supervisor, Communicable Disease Unit

Birdie M. McKee, R.N., B.S., Red Cross Nursing Service, 14 Park Ave., Caldwell, N. J., Supervising Nurse

Eleanor J. Pingrey, 2019 E. 3rd. Ave., Durango, Colo., Student, Univ. of Colorado

Jeanne Richie, R.N., B.S., R.F.D., Rialto, Calif., Public Health Nurse, Imperial County Health Dept.

Eula P. Rogers, 4173 S. Elati, Englewood, Colo., Supervisor of Public Health Nurses, Arapahoe County

Jeane W. Walvoord, R.N., M.S.P.H., c/o American Mission, Amoy, South Fukien,

China, Supervisor of Public Health Nursing, Board of Foreign Mission of Reformed Church

Epidemiology Section

NEWS FROM THE FIELD

REGIONAL CONFERENCE ON LOCAL HEALTH UNITS

The first in a series of regional conferences to get home town action on the problem of getting every person in every county under the umbrella of local health protective services was held in Mitchell, Ind., on April 21 and 22. Under the sponsorship of the National Health Council, and planned with the co-operation of the health departments of the five states of Indiana, Kentucky, Michigan, Ohio, and Wisconsin, this conference brought together representatives of a variety of voluntary health and citizen agencies.

The Indiana State Health Department was host to the conference and made arrangements for the details of recording, publicity, stenographic, and other services. It also had the largest delegation.

Except for several resource persons the conference group was selected by the respective state health officers to bring together those interests that could develop most effectively favorable opinion for extending local public health services in their states. The keynote of the conference was accented by Bailey B. Burritt, Executive Director of the National Health Council, in his opening address with a quotation from Woodrow Wilson to the effect that, "The highest and best form of efficiency is the spontaneous coöperation of free people."

The plan of the conference was for a general session the first morning to explore the problem areas to which working committees should devote the afternoon session. The problem areas were resolved into three major groupings, each of which was assigned to a working committee. These committees, each with a discussion leader and a recorder, grappled with their problem during an after-

noon session. Their reports were then presented to the entire conference at an evening session.

The three main problems were defined as (a) securing public demand and support, (b) organization of a plan for each community including a consideration of the legislative and political factors affecting the development of such a plan, (c) accomplishing the plan through provision of adequate funds, a strong state health department, and qualified personnel. The discussions were active, with everyone participating and with colorful illustrations of specific conditions or achievements in the various states. There was universal agreement that local upsurge must be stimulated; that lasting results cannot be achieved by superimposing a state program upon local lack of knowledge and interest. The state's role, both of official and voluntary agencies, is that of stimulation, information, consultation, and assistance. The importance of local assistance in recruitment of personnel was also emphasized as was the necessity for training facilities. Inadequate salaries and an anomalous situation with respect to prestige, particularly as it affects the medical profession in public health, are the chief stumbling blocks to recruitment of personnel in adequate numbers.

The second morning discussions were carried on by the separate state groups. Here the plan was to apply the general findings of the previous day to the particular problems of the respective states. On this day the afternoon was devoted to the state group reports and general discussion of them and to a summing up.

The various state situations were reviewed. Michigan, for example, has nearly 100 per cent coverage but is currently struggling with the problem of personnel and with political currents that

are detrimental to effective completion of coverage. Kentucky, because of the constitutional limitations on salaries of public workers, is under the necessity of holding back demands for additional county units because of failure to secure personnel.

The Wisconsin Legislature has just passed a permissive health unit law and many citizen agencies throughout the state are demanding local action. There is hope that many areas may be organized in the near future. A meeting of 25 representative citizens was held on May 12 to develop a strategy for getting widespread public understanding of and demand for the services of local health departments throughout the state.

Ohio is handicapped by its public health law dividing the state into 203 health districts, a separate one for each city of 5,000 or more, and one for each county outside these cities. Since the law provides for consolidation of districts, however, the state health department has developed a plan for 37 county, city-county, and multi-county health departments to replace its 203 health districts. Some score of voluntary and citizen agencies in the state plan a survey of the various state public health laws as a basis for proposing amendments to the Ohio law.

Indiana's recent legislature passed a permissive health unit act and there is hope that the 1949 legislature will provide state aid to local health departments. One bi-county department has already been organized and sufficient income has been created in enough areas so that if they become organized half of the state's population will be served instead of the less than one-quarter now served.

In summing up the two day discussions, Mr. Burrill used Haven Emerson's Catechism on "What are the Seven Steps to the Temple of Health," which was used as display at the Princeton Conference on Local Health Units in

September, 1947. These seven steps are:

1. A plan by the state health department
2. The organization of a state-wide citizen committee of voluntary and citizen agencies and approved by the governor
3. Completing legislative authority
4. Legal authorization for personnel and salaries
5. Agreement upon tax sources of support—local, state, and federal, for the local health department
6. Recruitment and training of personnel
7. Local community health council follow through to secure results and tax support

About 50 persons attended the conference. Chairmen and reporters of problem and state committees were drawn from the conference membership. Delegates represented parent-teacher associations, the Farm Bureau, CIO, state medical societies, Federation of Women's Club, American Association of University Women, state branches of such national agencies as the National Tuberculosis Association, National Society for Crippled Children, National Foundation for Infantile Paralysis, American Red Cross, as well as representatives of official health agencies. State health commissioners of three of the five participating states attended the conference.

The National Health Council staff is now analyzing the results of the conference with a view to determining whether it represents a pattern for similar conferences in other regions of the country.

AWWA OFFICERS

The following officers of the American Water Works Association were elected recently to take office on May 7, 1948:

President—Linn H. Enslow, Editor, Water and Sewage Works

Vice President—A. P. Black, Professor of Chemistry, University of Florida

Treasurer—William W. Brush, Editor, Water Works Engineering

Harry E. Jordan is the permanent secretary of the Association, which has headquarters at 500 Fifth Avenue, New York.

AUSTRALIA'S MEDICAL CARE PROGRAM INCLUDES PHARMACEUTICALS

According to a federal Act, passed in 1947, pharmaceutical benefits now are included in the Australian government's health and social services program. Compiling and reviewing at regular intervals a formulary defining the scope of the benefits is in the hands of a permanent committee, of seven members, including three medical practitioners and pharmacologists and pharmacists.

A prescription, in authorized form consisting of items included in the formulary, and signed by a physician, will be presentable without charge to the patient to any chemist or dispensary approved under the Act.

In reporting on this development, the Australian Information Service says, "It is hoped that the public will receive a service not only as good as present practice, but actually better, because of the elimination of drugs long superseded."

DR. PARRAN TO CHILDREN'S FUND

Thomas Parran, M.D., who retired as Surgeon General of the U. S. Public Health Service on April 6, leads a temporary mission to the Far East of the United Nations International Children's Emergency Fund. He is making a study preparatory to the extension of special forms of Children's Fund aid to mothers and children. Dr. Parran's mission is in line with the Fund's Executive Board recent directive that future allocations give special consideration to the needs of children in countries outside Europe. Five and a half million dollars has already been allocated for a child aid program in China, and a million and a half for other Far Eastern Countries.

Dr. Parran's tour of duty, which began late in April and will take about two months, will cover the Philippines, China, Hong Kong, French Indo-China, Malaya, Singapore, Indonesia, Thailand, Burma, Ceylon, India, and Pakistan.

PROFESSOR STARIN RETIRES

William A. Starin, Ph.D., Chairman of the Department of Bacteriology, Ohio State University, was honored at a dinner in Columbus on May 8. He will retire from active service at the end of the academic year, after 38 years of teaching at the university. He is known particularly for his work on filtrable viruses, pathogenic fungi, immunology, and pathogenic bacteriology. He has been a member of the American Public Health Association since 1933 and a Fellow since 1943.

The William A. Starin Lectureship has been established at the university by Professor Starin's friends and former students. Those wishing to share in this permanent tribute may send contributions to Dr. Margaret D. Heise, Department of Bacteriology, Ohio State University, Columbus, Ohio.

NEW BI-COUNTY HEALTH DEPARTMENT IN ILLINOIS

Fred O. Tonney, M.D., is the Health Officer of the recently organized joint health department of Effingham and Shelby counties in Illinois. This department was established as a result of a referendum in 1946. The combined population of the two counties in 1946 was nearly 50,000.

ARMY MEDICAL DEPARTMENT EXPANDS TRAINING PROGRAM

The United States Army Medical Department announces an expansion of its educational and training program, the primary goal of which is an unequalled high standard of medical care for the U. S. Army. Public health training is part of this program with courses in public health, sanitary engineering, hospital administration, and related fields. Medical officers who desire to be certified by American specialty boards can participate in officially recognized programs leading to examination for specialist certification, including the In-

terim Specialty Board in Preventive Medicine recently announced for the medical officers of the services.

All six Corps of the Army Medical Department—Medical, Dental, Nurse, Veterinary, Medical Service and Women's Medical Specialist Corps—and both enlisted men and women and commissioned officers, are represented in these training courses. The Army Medical Department arranges for personnel to take the courses and pays the tuition when required. Full pay and allowance is offered for the period of study at civilian and Army institutions.

PEDIATRICS, A NEW JOURNAL

In January, 1948, *Pediatrics*, the Journal of the American Academy of Pediatrics, began publication. It is "the medium of expression of the Academy to the medical profession and the public," "brings to its readers a comprehensive survey of the pediatrics field," and "publishes original articles on scientific and clinical investigations in the field of pediatrics."

Hugh McCulloch, M.D., is the Editor-in-Chief. Contributing editors are Leona Baumgartner, M.D., of New York, John P. Hubbard, M.D., Director of the Academy's study of child health services, and Dr. Felix Hurtado of Havana.

Annual subscription to this new monthly journal is \$10.00. Manuscripts, books for review, and correspondence concerning editorial matters should be sent to the Editor-in-Chief, 325 North Euclid Ave., St. Louis 8, Mo.; correspondence concerning subscriptions, advertising, and business matters to Charles C. Thomas, Publisher, 301-327 East Lawrence Ave., Springfield, Ill.

CECIL K. CALVERT, 1886-1948

On April 19, 1948, Cecil K. Calvert died at the age of 61. For forty years he served in various capacities in water purification work in Indianapolis, Ind.

In 1908, Mr. Calvert joined the staff of the Indianapolis Water Company becoming Superintendent of Purification in 1936, which position he held at the time of his death. Among his more prominent accomplishments in the field of sanitary engineering was his work with the American Water Works Association, in which he was Chairman of the Water Purification Division and of the Committee on Control of Chlorination. He joined the American Public Health Association in 1927 and became a Fellow in 1946.

LONG ISLAND COLLEGE CONCLUDES POST-GRADUATE COURSE IN INDUSTRIAL MEDICINE

The Fifth Postgraduate Course in Industrial Medicine offered by the Department of Preventive Medicine and Community Health, Long Island College of Medicine, Brooklyn, N. Y., was concluded April 16 after running for two weeks.

Thomas D. Dublin, M.D., Professor and in charge of the course reports that the total enrollment of full- and part-time students was 75, the second largest of the postgraduate courses so far offered. Thirty-one of the matriculants were physicians, 26 nurses, and 18 members of other professions. Students from Belgium, China, and Egypt were included, as were representatives of 26 different organizations in 6 different states. The lectures given for the students are expected to be published in a volume of proceedings.

KANSAS PUBLIC HEALTH ASSOCIATION MEETS

The Kansas Public Health Association held its Sixth Annual Meeting in Topeka on April 16 and 17. At the meeting a feature was a dinner honoring Charles H. Lerrigo, M.D., for forty-seven years of public health service in the state.

The officers who will serve the Kansas

society during the forthcoming year are:

President—M. Leon Bauman, M.D., Parsons

President-elect—James M. Mott, M.D., Lawrence

Secretary-Treasurer—Evelyn Ford, Topeka

The 1949 Annual Meeting of the K.P.H.A. will be held in Pittsburg April 25 to 27.

MICHIGAN PUBLIC HEALTH ASSOCIATION

At its recent annual meeting the following officers of the Michigan Public Health Association were elected:

President—Mildred Cardwell, R.N., Ingham County Health Department

President-Elect—E. Frank Meyer, D.V.M., Grand Rapids

Vice-President—Joseph G. Molner, M.D., Deputy Commissioner and Medical Director, Detroit Department of Health

Secretary-Treasurer—Marjorie Delavan, Director, Bureau of Education, State Department of Health

Representative on Governing Council, A.P.H.A.—Kenneth R. Gibson, D.D.S., Dental Director, Children's Fund of Michigan

ILLINOIS PUBLIC HEALTH ASSOCIATION ANNUAL MEETING

The Illinois Public Health Association held its 8th Annual Meeting in Chicago on April 15 and 16. The attendance was well over 500. New officers were elected as follows:

President—Maude B. Carson, R.N., Springfield

President-Elect—Baxter K. Richardson, Springfield

Secretary-Treasurer—Harold M. Cavins, Ed.D., Charleston

WHO CHARTER RATIFIED

The final meeting in Geneva of the Interim Commission of the WHO on February 7 was climaxed by an announcement that 29 United Nations, 3 more than necessary, had ratified the charter of the WHO. By April 7, 26 of the ratifications had been deposited with the United Nations, thus bringing the WHO officially into being. In addition, 8 nations not members of the

United Nations have ratified the constitution. This announcement was made by its Chairman, Dr. Andrija Stampar of Yugoslavia, who announced that the first session of the World Health Assembly will open in Geneva probably on June 24, 1948.

The United States is not among the member nations that have ratified the charter, the House Rules Committee having tabled the resolution indefinitely on March 12.

The budget of \$6,000,000 adopted by the Interim Commission provides for fellowships, teaching equipment, and medical supplies to meet post-war health problems, world-wide campaigns against malaria, tuberculosis, and venereal diseases, and a top-priority program for mother and child welfare.

LATIN AMERICAN NUTRITION CONFERENCE

In an effort to encourage all Latin American countries to provide their peoples with a healthy diet, the Food and Agriculture Organization of the United Nations will hold a regional meeting of leading nutrition workers at Montevideo, Uruguay, starting July 28. Delegates have been invited from 18 Latin American countries and from France, the Netherlands, the United Kingdom, and the United States. The Argentine Republic, which is not a member of FAO, and interested international organizations have been asked to send observers.

The delegates will determine the gaps in existing knowledge about dietary habits, the state of nutrition, and the prevalence of deficiency diseases. They will plan measures to fill these gaps and attempt to develop and dovetail their national plans into a concerted attack to improve the nutrition of the people.

Serious malnutrition due to deficiency of protein, certain minerals, and vitamins, exists in many Latin American countries. Despite the fact that total

food production has increased in parts of Latin America, a large proportion of the population still exists on inferior and ill-balanced diets.

Recommended by the FAO Geneva Conference last summer, the 10 day meeting is the second of a world series planned by FAO on nutritional problems. The first, held in the Philippines in February, 1948, was concerned mainly with ways and means of improving rice diets in South East Asia.

PROGRESS IN STREAM POLLUTION CONTROL

About the time you read this paragraph, the Ohio River Valley Water Sanitation Compact will become effective. This Compact commits 8 states, comprising the Ohio River system, to a program of stream pollution abatement. To aid in carrying out the Compact a "Symposium on Water and Waste Treatment" will be held on October 16, 1948, in the Engineering Society Headquarters Building, Cincinnati, Ohio, for the purpose of providing a medium for disseminating the technical information essential to the solution of stream sanitation problems. For further information, write to Robert C. Head, Publicity Representative, American Institute of Chemical Engineers, 795 Greenville Avenue, Glendale, Ohio.

CANADA'S PUBLIC HEALTH FILM SURVEY

Supplement 3 of the *Medical and Biological Films Catalogue*, of the National Film Board of Canada, brings up to date the master list published in March, 1945, and two subsequent supplements published in July, 1946, and March, 1947. As with the previous lists, the films are classified according to the public health specialty such as industrial health and safety, cancer, personal hygiene, with the names and brief descriptions of specific films under each heading, also a comment of the suitability of each film for certain purposes. Ad-

ditional information may be obtained from the Distribution Officer, Health and Medical Films, National Film Board, Ottawa.

NEW ANTIBIOTICS DIRECTORY

Second edition of *Antibiotic Substances, Their Biological and Chemical Properties*, has recently been published by the antibiotic section in the Division of Research Grants and Fellowships, National Institute of Health. It contains current material on source, biological activity, unit, potency, and miscellaneous properties of more than 150 antibiotic substances ranging alphabetically from actidione to viridan. The compilation includes a number of unnamed factors, as well as named chemotherapeutic agents from non-microbial forms (quercetin, tomatin, etc.). First edition of the guide was published early in 1947.

NEGRO HEALTH AND MEDICAL CARE

In January the Health and Medical Care Collection of Meharry College was a year old. By way of celebrating its first birthday it published an annotated list of books, periodicals, pamphlets, leaflets, and articles relating specifically to the health of the Negro. With the coöperation of state health departments, national organizations, and individuals the Collection now numbers nearly 500 items.

Thomas A. LaSaine, M.D., the director, renews his invitation to share with this Collection available material concerning the health of the Negro. The address is Health and Medical Care Collection, Meharry Medical College, Nashville 8, Tenn.

DR. NORTON SUCCEEDS DR. REYNOLDS AS NORTH CAROLINA STATE HEALTH OFFICER

The retirement of Carl V. Reynolds, M.D., Secretary and State Health Officer of North Carolina, Raleigh, as of July 1, 1948, has been announced. Dr.

Reynolds will move to California and live in Altadena.

John W. R. Norton, M.D., M.P.H., of Chattanooga, Tenn., has been appointed to succeed Dr. Reynolds. Dr. Norton is a native of North Carolina, born in 1898, a graduate in medicine of Vanderbilt University in 1928, and with a Master's degree in Public Health from the Harvard School of Public Health in 1936. Dr. Norton served four years as Health Officer of the City of Rocky Mount, N. C., and served for several years with the North Carolina State Board of Health in the Divisions of County Health Work and Preventive Medicine. Dr. Norton served in the Army Medical Corps during World War II, since which time he has been Chief Health Officer of the Health and Safety Department, Tennessee Valley Authority, Chattanooga, Tenn.

DEATH OF DR. RUPERT BLUE

Rupert Blue, M.D., Ex-Surgeon General of the U. S. Public Health Service, died on April 12 in Charleston, S. C., at the age of 80. Dr. Blue retired in 1932 after 39 years in the Service, 12 of them as Surgeon General by appointment of President Taft in 1912 and reappointment by President Wilson in 1916.

Dr. Blue was noted for his bubonic plague campaigns in San Francisco in the early 1900's. He conducted extensive rat extermination drives there. During the first World War he was adviser on sanitation for military establishments in the United States. In 1923 he was American delegate to the Opium Conference of the League of Nations.

Dr. Blue became a member of the American Public Health Association in 1912 and a charter Fellow in 1922.

VIRGINIA'S MODEL ALCOHOLIC CARE BILL

The Virginia Legislature, one of the few that meet in the even numbered

years, has enacted a bill that sets up a Bureau of Alcohol Studies and Rehabilitation in the State Department of Health. Including an appropriation of \$200,000 for the biennium, the new law places the initial responsibility for the study and treatment of alcoholics upon medical schools and hospitals.

The first of several state research centers will be located at the Medical College of Virginia in Richmond where patients will receive both hospital and clinic care.

In reporting the Virginia law, Joseph Hirsh, Acting Director of The Research Council on Problems of Alcohol, said it would "undoubtedly serve as a model for the rest of the country." He pointed out that none of the other seven states that have already established medical programs for the care of alcoholics provides such an integrated program as that of Virginia.

EDUCATIONAL OPPORTUNITIES IN INDUSTRIAL HYGIENE

Industrial Hygiene Newsletter for April, 1948 (Vol. 8, No. 4), has a list of schools that give complete courses in industrial hygiene. Classified into the 9 U. S. Public Health Districts and into courses for physicians and dentists, nurses, engineers, and chemists, this list gives the name and address of the school and a short description of the courses, the time required to complete them, and degrees offered.

The Industrial Hygiene Division of the U. S. Public Health Service, which publishes this monthly *Newsletter*, carefully warns that the list is not a complete one. It is recommended to readers, however, as the most complete such listing that has come to hand.

PUBLIC HEALTH SECTION OF EXCERPTA MEDICA

Excerpta Medica, the project for abstracting the world's medical literature was mentioned in the August, 1947,

vacated by Dr. Scheele. Dr. Heller's position in the Division of Venereal Diseases will be assumed by Dr. Theodore J. Bauer who is at present on duty with the Chicago Board of Health as municipal venereal disease control officer.

INSTITUTE IN PUBLIC HEALTH ADMINISTRATION

The University College of Northwestern University, in coöperation with the U. S. Public Health Service, has announced a two week Institute in administration for principal administrative officers of state and local health departments. The Institute, July 12-23, will concern itself with administrative problems, and its registration is limited to 40 persons who must be health officials with managerial responsibilities.

The Institute was planned at an earlier regional conference of state and local health officers to meet gaps in the health officer's knowledge of such items as press and public relations, personnel administration, budget presentation, etc. Registration fee for the Institute is \$100, of which \$10.00 must accompany registration request. Provision will be made for room and meals in Abbott Hall of the university at \$60 per person for the period. Application should be made before June 21 to the University College, Northwestern University, 710 Lake Shore Drive, Chicago 11, Ill.

"THE AMERICAN ENGINEER" UNDER NEW MANAGEMENT

The National Society of Professional Engineers announces the appointment of Franklin F. Page as Editor of the *American Engineer*, the monthly publication of that Society. Prior to joining the staff of the NSPE, Mr. Page had had considerable experience in newspaper work and has been editor of *Constructor and Engineer*, a publication serving the northwestern part of the United States.

PERSONALS

Central States

RICHARD F. BOYD, M.D., M.P.H.,* who has served for some years as Chief of the Division of Local Health Administration, Illinois State Department of Health, Springfield, Ill., has resigned, effective May 17, to accept a position of Medical Officer, Welfare and Retirement Fund, United Mine Workers of America with offices at 900-15th Street, N.W., Washington 5, D. C. In this capacity Dr. Boyd will be associated with R. R. SAYERS, M.D., who is Chairman of the Medical Advisory Board, and who is responsible for developing plans for the medical care and hospitalization of approximately 400,000 bituminous coal miners in 26 states.

DORIS G. CHANDLER, M.P.H.,† has been appointed Director of Health Education of the National Society for the Prevention of Blindness, New York, N. Y. For the last few years she has been Executive Secretary of the Metropolitan Health Council of Dayton and Montgomery Counties, Ohio.

CHARLES T. DOLEZAL, M.D.,† has been appointed Assistant Director and Secretary of the Council on Professional Practice of the American Hospital Association, Chicago, Ill., to succeed HUGO V. HULLERMAN, M.D.,* resigned. Dr. Dolezal was formerly Superintendent of City Hospital of Cleveland, Ohio.

WINSTON H. TUCKER, M.D.,* Commissioner of Health of Evanston, Ill., represented the A.P.H.A. at a meeting on April 5 and 6 on a Subcommittee of the American Medical Association Council on National Emergency Medical Service, for the purpose of planning for the most effective use of the overall medical resources of the nation in case of another national emergency. HAROLD S. DIEHL, M.D.,* Dean of the University of

Minnesota School of Medicine, Minneapolis, is Chairman of the Committee.

JOSEPH R. WAGNER, widely known in the fields of biochemistry and nutrition, has joined the staff of the Quartermaster Food and Container Institute for the Armed Forces, Chicago, Ill., as Chief of the Fruit and Vegetables Branch, Food Development Division. He was formerly head of the Nutritional Research Section in the General Laboratory of Libby, McNeill & Libby, Blue Island, Ill.

E. EUGENE WEHR, M.D., is now Assistant Health Commissioner in the Cincinnati, Ohio, Department of Health. WATSON DERSHAM† recently took up his duties as Health Educator of the Department.

WALDO W. WILMORE† has been appointed Associate Executive Secretary of the Kansas Tuberculosis and Health Association, Topeka. He was formerly Personnel Officer under FLOYD C. BEELMAN, M.D.,* Kansas State Board of Health.

E. V. THIEHOFF, M.D.,* has been appointed Professor and Head of the Department of Public Health and Preventive Medicine of the University of Kansas, Lawrence. He resigns as Commissioner of the Peoria City, Ill., Health Department on April 1.

Eastern States

STANHOPE BAYNE-JONES, M.D.,* who is President of the Joint Administrative Board, New York Hospital-Cornell Medical Center, New York City, has been awarded the insignia of Honorary Commander of the Military Division of the Most Excellent Order of the British Empire. The presentation was recently made in Washington by Lord Inverchapel, Britain's Ambassador.

CONRAD BERENS, M.D., of New York City was elected President of the Pan

American Association of Ophthalmology at the Third Pan American Congress of Ophthalmology held in Havana, Cuba, January 4-10.

ELSIE M. BOND has retired as Assistant Secretary of the State Charities Aid Association, New York, N. Y., after 25 years of service with the Association. Miss Bond served as the legislative representative of the S.C.A.A. in Albany during the administrations of Governors Alfred E. Smith, 1923-1929; Franklin D. Roosevelt, 1929-1932; Herbert H. Lehman, 1933-1942; and Thomas E. Dewey, 1943-1948.

THOMAS E. CONNOLLY was recently appointed Executive Secretary of the Onondaga Health Association, Syracuse, N. Y., to succeed ARTHUR W. TOWNE, retired recently as Executive Secretary of the Association after 24 years of notable service.

VLADO A. GETTING, M.D.,* was reappointed April 7 as Commissioner of Public Health of Massachusetts by GOVERNOR ROBERT F. BRADFORD. Dr. Getting, who is also President of the State and Territorial Health Officers Association, was first appointed to his present post in 1943 after having served as Worcester City Health Officer.

CUSHMAN D. HAAGENSEN, M.D., Associate Professor of Surgery at Columbia University's College of Physicians and Surgeons, New York, N. Y., has been named Coördinator of Cancer Teaching for the college's cancer research program. He is developing a project on cancer research designed to obtain close coöperation among major divisions of the university's medical sciences and clinical departments.

JOSEPH HIRSH,* who has been on leave of absence to WHO, has returned to the Research Council on Problems of Alcohol, New York, N. Y., and is now its Acting Director, following the

resignation of LYMAN C. DURYEA, M.D.,* to return to active service with the U. S. Army Medical Corps. Mr. Hirsh also serves as consultant to WHO.

THEODORE G. KLUMPP, M.D., President of Winthrop-Stearns, Inc., New York, N. Y., was elected President of the American Pharmaceutical Manufacturers Association at its recent annual convention in Havana, Cuba.

ESMOND R. LONG, M.D.,* Director of Medical Research and Therapy, National Tuberculosis Association, and Director of the Henry Phipps Institute, Philadelphia, Pa., has been named Editor-in-chief of the *American Review of Tuberculosis*, official journal of the National Tuberculosis Association's Medical Section, The American Trudeau Society, to succeed the late MAX PINNER, M.D.

WALSH McDERMOTT, M.D., Associate Professor of Medicine, Cornell University Medical School, New York, N. Y., has been appointed to the newly created post of Managing Editor of the *American Review of Tuberculosis*, New York City.

GORDON W. MOLYNEUX,* formerly Supervising Milk Inspector for the Westchester County, New York, Department of Health has resigned from the county service to manage the Rock Gate Dairy Farm, Bedford Hills, N. Y.

HOWARD A. RUSK, M.D.,† New York, N. Y., received the first annual Survey Award for "an imaginative and constructive contribution to social work" on April 22, for his outstanding work in translating into civilian life what was learned about rehabilitation in the armed forces. The award was presented by EDUARD C. LINDEMAN, M.D., for *The Survey* Midmonthly during the 75th Anniversary Meeting of the National Conference of Social Work held in Atlantic City, N. J.

AUSTIN SMITH, M.D.,* Secretary of the Council on Pharmacy and Chemistry of the American Medical Association, Chicago, Ill., has been appointed Science Editor of *American Druggist Magazine*, New York, N. Y. Dr. Smith will continue his work with the A.M.A., and will maintain his office at the A.M.A.'s headquarters in Chicago.

Southern States

DANIEL BLAIN, M.D., formerly Chief of Neuropsychiatric Service for the Veterans Administration, Washington, D. C., has accepted the newly established position of Medical Director of the American Psychiatric Association.

FRANCIS G. BLAKE, M.D., Sterling Professor of Medicine at Yale University, New Haven, Conn., has been appointed to head the Medical Science Committee of the Federal Research and Development Board, Washington, D. C. Dr. Blake is a member of the Lasker Awards Committee, A.P.H.A.

JOHN M. DAVID† has accepted a position with the Layne-Atlantic Well Company, Albany, Ga. He was formerly Regional Engineer with the Georgia State Department of Public Health in the Southwest Region of Georgia.

LAWRENCE MACHEMER FISHER,* Sanitary Engineer Director of the Public Health Service, was recently appointed by PRESIDENT TRUMAN to the Interstate Commission on the Potomac River Basin. Other commission members serving by presidential appointment are C. C. BURGER, Department of the Army, and ABEL WOLMAN,* Johns Hopkins University.

ROBERT A. HINGSON, M.D., has been

* Fellow A.P.H.A.

† Member A.P.H.A.

Some Concrete Problems of Health Administration*

A GROUP of outstanding health administrators (on state, city and county levels) were asked to prepare for

* Special Review article prepared at the request of the Editorial Board.

the JOURNAL brief statements with regard to specific problems of administration which they had faced during the past year. The general significance of these contributions is discussed editorially on page 1008 of this issue.

Staff Education in Chicago

HERMAN N. BUNDESEN

During the depression years, the food inspection section of the Chicago Health Department had been operating with a totally inadequate force, due to insufficient appropriations.

Previous to the passage of the appropriation bill for the year 1947, it was the practice of the Board of Health, in submitting budget estimates for each year, to ask for additional personnel for the food inspection section in order to maintain a reasonable inspection standard. However, these requests for funds to employ additional personnel went unheeded year after year.

During the year 1946, the U. S. Public Health Service made a survey of the activities of the Health Department of the City of Chicago, together with other official and voluntary health agencies

in the city and Cook County. Among the recommendations made in the report of that survey was that the food inspection section be provided with added personnel, and that a revision of the food control ordinance, based on the requirements of the U. S. Public Health Service recommended code, be adopted by the City Council. As a result of this report, twenty-five additional food inspectors and three additional supervisors were provided, and the revision of the *Municipal Code* was made.

The coming of new inspectors upon the staff necessitated a change in the existing in-service training program for the purpose of teaching these new men the fundamentals of sanitation and inspection technique.

At about the time these men were first

employed, a program of food handler education was being carried on in co-operation with the Chicago Restaurant Association. Newly appointed food inspectors were first required to attend these food handler courses, in order that they might acquaint themselves with what was necessary from the food handler's standpoint. Following this, an intensive course in ordinance requirements and recognition of satisfactory compliance was carried on. Instructions were given especially as to the public health reasons for ordinance requirements. Inspectors were required to spend some time in the laboratory to observe the method of making plate swab counts and to learn the technique of making swab tests.

Newly appointed inspectors were sent out in groups of three with a supervisor accompanying each group, in order to observe the supervisor's method of making food inspections; then, after a week, the new men made the inspections themselves under the personal observation of the supervisor. Following this part of their training, they were required to spend at least 2 weeks in the field with qualified inspectors, and in some cases more time, until they were able to make a satisfactory inspection and report. The In-Service Training School has continued to operate after the new inspectors completed this training and were out working on their own responsibility. Weekly sessions of the school were held to give them specialized training on such subjects as milk inspection, meat inspection, poultry inspection, refrigera-

tion of foods, food poisoning, disinfection of utensils, plumbing and back siphonage, particularly as applied to restaurants and hotels, construction of dishwashing machines, courtesy and tact in dealing with the public, fumigation of foods for destruction of vermin infesting the foods, procedures in license approval, preparation of drastic measures where warranted, and other subjects with which the food inspector should be familiar.

It is the opinion of the Chicago Health Department that food inspectors do not become efficient merely by grace of an appointment. In addition to such knowledge and experience as a man may have when he receives an appointment, he must also have a will to learn and the capacity to absorb and use the knowledge that is given to him in the In-Service Training School and by supervisors in the field.

The food inspector, on entering a food establishment, is the representative of the Board of Health. As such, he should be able to conduct inspections in such a way as to render to the citizens of his community all the service which the city ordinance requires the head of the Health Department to render in food establishments and to reflect credit upon the department which he represents.

There is no set formula by which one can convert a new inspector from raw, untrained material to the ideal which is needed. It is only by constant education within our own service that this goal can be reached.

Housing the Health Department in Detroit

BRUCE H. DOUGLAS

Local conditions will have much to do with the housing of the health department. Much will depend too on whether

it is a small or a large health unit, a state health department, a county unit in a rural area, or a municipal depart-

ment serving a populous urban community. It would seem, however, that there are certain principles that should prevail in providing housing for a health department in order to contribute good public health administration in the best interest of the people.

Too often the space provided for a health department is some inaccessible, reconverted building or basement location which is assigned because of limited budget or lack of vision by public officials. Frequently there is little appreciation of the needs of the health department or of the place it should occupy in the area to be served.

Of course it is to be conceded that the housing of a health department is not as important as the matter of having well qualified personnel, but nevertheless, appropriate housing will make for better service and greater appreciation by all concerned, including the public, as to the importance of the role the health department plays in the community.

With new public building programs under way or projected, it is timely to give consideration to this matter. Several large cities are planning new provisions varying from a separate building for public health administration to combination with one or more other governmental departments or, finally, inclusion in a large municipal building where all administrative offices of the city or the city-county government will be housed.

There are points in favor of each of these arrangements as well as points against them. It is also true that variations in the functions performed by different health departments may affect

the arrangements for housing. For instance, when the health department is responsible for the operation of a hospital or hospitals, it may be desirable to have the administrative offices of the health department located in or near the hospital plant.

The principal point in favor of a municipal health department being housed with other city administrative offices is the convenience afforded those who must secure certain permits, license approvals, and similar records or information, often related to other public departments, so that if housed together, the individual visitor can transact all his business within one building.

Much of the work of a health department, however, is not related directly to other departments of government. For example, services to physicians, provision for clinics, and issuance of vital records make it highly desirable to have these activities housed within easy access for those coming to the health department for such services. In addition, the ease with which field staff may come and go in carrying out their duties must be given consideration. Of course, in a large city some services can and should be decentralized by providing health centers for certain functions in locations where they are near the people needing the services and out of which the field staff may more readily work. These may profitably be located in or near hospitals or medical centers.

There is therefore good justification for the health department having its own building properly located, thereby emphasizing the importance of its services as well as making possible greater accessibility for those it serves.

Coöperation with Voluntary Organizations in Montgomery County, Maryland

V. L. ELLICOTT

The year 1947 has shown no decrease in voluntary organizations. Each one still remains a pressure group for a special interest. The health officer's attitude is usually one of caution so as to keep these people from getting out of hand. My suggestion is to take the risk of encouraging them and working with them in order to get the advantage of their public support.

The progressive health officer does not want a static health program but one geared for growth, the growth being directed toward unmet health needs. So few health departments approach adequacy at present that provision for growth should be a basic principle of organization. This means successive increases in personnel and budgets. The simplest way to obtain them is by direct request of the health officer to the county commissioners or other appropriating body, the appeal being based on a clear, logical statement of needs. This appeal often fails, however, because the county commissioners expect new proposals to be supported by public interest as well as logic. Can the health officer utilize voluntary organizations to gain this support?

Since voluntary organizations may be pulling in different directions, the health officer's problem is to get them to pull together and pull with him. In Montgomery County we believe we have found an effective way of doing this. Each organization is encouraged to take

an interest in the general county-wide program in addition to its special interest. Each of our eleven local public health lay committees, for example, does this by recognizing the dependence of the local public health nurse on the county nursing group. As a result, local committees vigorously supported the 1947 successful drive for more adequate nursing salaries. The Tuberculosis Association and many other similar groups are joining in a concerted effort to secure a new county health center in Rockville. The most important part of this county-wide interest, however, is the agreement among the organizations and the Health Department as to what the principal health needs are and what is the order of their importance. We depend largely upon the American Public Health Association's *Evaluation Schedule* for this important step. The *Schedule*, we point out, represents the opinions of leading nation-wide health authorities. It therefore has a common appeal to all intelligent public spirited citizens, the same appeal as the recommendations of an important survey. It also proves that the current proposals for meeting the needs are something more than the special interests of the health officer. This approach—agreement between voluntary agencies, other citizen groups, and the health officer—has one other advantage—it works better with each year of usage.

Procurement of Personnel in Massachusetts

V. A. GETTING

Today health agencies are faced with a critical shortage of professional and technical personnel. An analysis of the factors for this ever increasing shortage reveals some of the major difficulties which make positions in public health unattractive to candidates seeking fields for professional training. This is true in spite of the fact that the words "public health" are more in the mouths of the everyday citizen, and the importance of health is better recognized than at any time previous. The obstacles in procurement of personnel must be overcome in order to procure staffs of adequately trained and experienced workers. Some of these difficulties may be summarized as follows:

1. Inadequate compensation — Although many health agencies have increased their salaries, the new salary schedules are still far below those which exist in the federal government agencies, in private practice, and in industry. Further substantial increases are indicated to overcome this obvious shortage.

2. Procurement policies—Merit systems and civil service procurement facilities cannot be relied upon exclusively. Health agencies, particularly state health departments and large voluntary agencies, must carry on detailed procurement programs from the secondary schools, professional and technical schools, to the public as well. Special personnel may be assigned to such programs.

3. Political interference—Freedom of exercise of the responsibilities of the health department is an absolute necessity. This must be unhampered by political interference if these positions in public agencies are to attract capable administrators. Too often administra-

tors drift from public to voluntary agencies because they are unable to discharge their duties without regard for political policies.

4. Dramatizing the job—General information which is both current and interestingly presented must be supplied to the public and the professions in order to make the positions and the work of health departments known. Today, as a matter of fact, only a relatively small number of physicians realize what health departments are doing. The significance of the work and accomplishments of health departments must be so dramatized and pictorialized that high school and college students will become enthusiastic about seeking positions in this field.

5. Security of tenure—With forty state health officers being replaced within a period of 5 years, it becomes apparent that the top administrative positions in public agencies are insecure. Because of this insecurity, positions of staff members become less desirable. With every replacement of a state health officer, policies are revised and responsibilities shifted, and there result obvious limitations in promotions and lack of continuity in the content of programs. Thus, measures must be taken to insure security of tenure at all administrative levels.

6. Merit system limitations — Although the primary purpose of merit and civil service systems is the procurement of qualified personnel, too often such systems, especially those established many years ago, offer serious limitations in the procurement of personnel. The merit system has too often become a method for protecting the employee rather than the service. Thus, veterans'

preference, residential requirements, and lack of educational qualifications may actually be deterrents to the procurement of adequately trained and experienced personnel. Some method must be found whereby the procurement work of merit systems is improved, so that promotional advancements may be offered to employees, and the limitations of lack of educational requirements, total veterans' preference and residential requirements may be limited, modified, or, if necessary, removed.

7. Retirement, vacation and sickness benefits—As human beings, employees have certain rights which must be respected and certain privileges which must be offered in order to attract them to positions in public service. The provision of adequate retirement systems, vacation allowances, and sick leave are

necessary, especially in today's shortage of personnel. A specialty board for physicians in public health may be an added inducement in the procurement of adequate personnel.

8. Physical facilities—Cheerful, well furnished, well lighted and ventilated offices are a necessity to any department. Too often a health department is located either in a basement or on a top floor of a public building, in the least desirable quarters available.

9. Recognition of services—Professional and technical workers require recognition in the form of credit and praise both in professional and public circles. Ample opportunities should be provided to reward faithful and hard working health department employees in recognition of their work and accomplishments.

Financing Local Health Departments in Florida

F. M. HALL

In 1911, Dr. Hermann M. Biggs,¹ then Commissioner of Health of the City of New York, said, "Public health is purchasable. . . ." He might have added, "but not at bargain-basement prices."

Too frequently state health departments, in their overzealous ambition to see local health service established in all areas of their jurisdiction, have sold the services at bargain-basement prices to the local appropriating bodies, assuming that, once the local unit was established, it would sell itself to the community. However, if a health department is to render in the community the worth while services expected, from the beginning, the financial support must be adequate. If this adequate financial support is not available, the local health department must depend upon poorly

trained individuals to render public health services to the community. This procedure results in poor services to the people and an undesirable impression given to the local governing body as to quantity and quality of work. Thus, a health department that is inadequately financed from the beginning is unable to render the services expected, and the local governing body and the community are unfavorably impressed by such services. So, when additional funds are sought, the appropriating bodies are not interested in increasing the appropriations.

The local governing body must be given, and must assume, full responsibility for its health department, both financially and for the services to be rendered, with a minimum of supervisory or advisory control from the state and

federal levels. To secure adequately financed health services in a community there must be local autonomy, but it should be impressed upon the local officials of the community that with local autonomy goes a local responsibility—a responsibility to finance its health services adequately; and a responsibility, after such financing, that services be rendered to the community in a manner that is in accord with good public health practices.

A goodly number of local health officers today find themselves in a situation that is rather difficult to meet. The individuals responsible for the establishment of the initial budget for the area based their estimates upon a monetary situation that is entirely different from the present-day inflationary period. Emerson² and his Committee on Administrative Practices used as a guide an overall cost of \$1.00 per capita for complete coverage of six minimum full-time services.

With our ever-broadening concepts of public health, one would readily come to the conclusion, even in a non-inflationary period, that \$1.00 per capita would be inadequate in financing a program based on these six phases.

Even to carry a program embracing the basic requirements, plus a few additional programs that are needed in any area, if we consider the inflation of the day, the minimum total per capita should be at least \$2.50, with \$1.00 as local contribution. Since the services of a health department are available to the entire health jurisdiction which it serves, the local support for such a health department should come from the governing body that directs the entire health jurisdiction unless special services are requested by a municipality that is within the area. Then, of course, those special services should be financed by the municipality concerned.

When the Alachua County Health De-

partment was established in 1944, an agreement was made by the Director of Local Health Service and a local committee spearheading the formation of this health department that 53 cents per capita locally would be adequate. The area would have, after state and federal contributions, \$1.11 per capita for public health services. As inflation has progressed over the years, the governing body has always reminded the committee and the Director of Local Health Service, of their original commitments. It is felt that many health officers find themselves, through no fault of their own, bound by such commitments. Even the governing bodies themselves have been caught short by the ever-increasing cost of government.

The health officer has open to him two courses:

1. Reduce staff with a resultant curtailment of program in order that salary increases may be met.
2. Secure additional funds to maintain an adequate public health program.

The latter method is preferred. The services rendered must be maintained at the present levels because the general public, having once become accustomed to an efficient public health program, would not understand why these services were curtailed.

The method of securing additional appropriations to augment the local budget must be determined by the health officer in his own respective area. He should be, and is, better informed of the local conditions than any other individual. If the health department has rendered a service that has been adequate and efficient, the difficulties in breaking down the barrier that was once built is much easier than if, from the beginning, the services of the organization have been considered inadequate.

It is well before an attempt is made to increase the appropriations, to evaluate your own health program both as to services rendered and allocation of

time to each service. This evaluation should include the accomplishments of the department. If it can be shown from such an evaluation that progress has been made, then the health officer has in his possession one of the strongest arguments that can be presented, a

local governing body in a justification of his request for additional funds.

Fiscal Relationships Between the State and Local Health Departments in California

W. L. HALVERSON

The question of the fiscal relationship between the state and local health departments is squarely before us in California. This is occasioned by the passage of the Public Health Assistance law providing \$3,000,000 for local health services, which became effective September 19, 1947. This appropriation is in addition to approximately \$1,000,000 of federal funds available for local health services.

Federal funds have been allocated largely on the basis of the extent of the problem in the various areas rather than on a formula basis. Density of population, percentage increase in population, morbidity and death rates for specific diseases such as venereal disease and tuberculosis, infant and maternal mortality rates, have all been factors in the decision as to the allocation of the various federal funds available. However, these factors have not been crystallized into a definite formula. Local health departments organized during the war period were allotted relatively large amounts per capita. In a survey of the situation, allocations to local health departments were found to vary from nothing to approximately 50 cents per capita. This can be defended during periods of stress such as the recent world war, but not on a continuing basis.

The formula for the allocation of the \$3,000,000 state fund for local health services is written into the law. Each county receives a basic allotment of \$16,000 or 60 cents per capita, whichever is less. The remainder, after subtraction of $7\frac{1}{2}$ per cent of the total for administrative and consultative services and training, is allocated to health departments meeting standards on a straight per capita basis.

In effect, counties with a population of 26,000 or less, and meeting minimum standards, receive approximately 82 cents per capita regardless of whether they operate individually or as a part of multi-county health units. Larger health jurisdictions receive a gradually decreasing per capita allotment, so that the metropolitan areas receive between 22 cents and 23 cents.

With this fairly liberal allocation of state funds, especially to the smaller health jurisdictions, we ask ourselves the question, "Should not a large proportion of the federal funds available for local health services also be allocated on a formula basis?" This administrative question has not been answered.

Our Public Health Assistance Act officially sets up a California Conference of Local Health Officers. This Con-

ference has at present four standing committees:

1. Administrative Practice
2. Fiscal Affairs
3. Personnel
4. Records and Reports

By law, the Conference must approve standards for local health service before establishment by the State Department of Public Health. We now propose that this Conference shall actively participate in the development of policy regarding the allocation of the federal funds. To this end, the Committees on Administrative Practice and Fiscal Affairs have developed proposals, with the assistance of the Divisions of Adminis-

tration and Local Health Service of the State Department of Public Health. These proposals were submitted to a meeting of the Conference, in February.

This department subscribes to and promotes the concept that local health departments should have a high degree of local autonomy. In order to accomplish this, it is essential that local health officers actively participate in the planning and execution of the total statewide public health program. It is anticipated that the present California law will go far in facilitating close working relationship between the state and local health departments, and will preserve the basic concept of local control.

Program Plans for Public Health Action in New York State

HERMAN E. HILLEBOE

One of the most important administrative problems of an official public health agency is the creation of orderly and well defined procedures and plans for public health action. Such a master working plan should have sufficient flexibility to permit such changes as circumstances and new knowledge require, but still present a uniformity of principle to which all public health workers can unanimously subscribe.

During the past year, the administrative staff of the New York State Department of Health has been engaged in an intensive review and evaluation of every program carried on by the department. The knowledge, experience, and thinking of the men engaged in and responsible for rendering health service to the public were presented in frequent conferences. Eventually, through change and interchange, through criticism and attack, through accumulation of data in all fields, specific public health program plans have been developed.

It should be recalled that a general health program in a nation, state, or local community is no better than the quality of the special programs which compose it. The emphasis on each disease should be determined by the seriousness of that disease in the particular area involved, making each special attack on a disease strong, effective, and well financed in relation to the problem. This is the surest way of building a general health program that will meet the needs of all the people and that will be accepted by them and permanently supported.

Before any disease which affects the general public can be controlled or eliminated, it is essential that professional public health personnel attack the problem under three main headings:

- A. The need for the program
- B. Objectives to be achieved
- C. Functions and techniques to be used to gain the objectives

When these three categories are ade-

quately considered, it is interesting to observe that public health program planners arrive at a remarkable uniformity of procedure and policy. The conventional approaches to public health administration and action; such as, control of communicable diseases, maternal and child health, vital statistics, nursing service, health education, and environmental sanitation, undergo a functional regrouping so as to permit an enlarged scope of program and the application of multiple techniques that will bring improved health services to the people.

To reach our important goals, particularly in providing health services in local communities, an official public health program should have three specific objectives:

1. Prevention and control of mass diseases
2. The collection and analysis of vital records
3. The maintenance and improvement of a healthy environment

Such specific objectives postulate certain well defined activities and functions and the application of definite techniques. These techniques can be described briefly as follows:

1. Study the extent of the public health problem. This includes the making of a complete survey of a community either by state or local personnel or by both. It will be necessary to review this evaluation at regular intervals, possibly as frequently as every year.
2. Recruit, train, and use competent personnel. Plans for improvement of local health services can be carried out only if adequate numbers of well qualified physicians, nurses, sanitary engineers, sanitarians, dentists, physiotherapists, health educators, medical-social workers, nutritionists, and others are available for employment. With the present-day shortage of personnel this requires that health departments obtain recruits who are untrained and give them the necessary academic or field training and experience to perform the duties of the several positions. Such training should not cease with employment but provision should be made for continuous-on-the-job training to keep the employees informed of newer methods and techniques, as well as to qualify them for more responsible positions.

3. Provide adequate modern quarters and the necessary equipment and tools of the profession.

4. Demonstrate the newest methods and consult with all participating groups. Frequently, local appropriating authorities "must be shown." Demonstrations can be given through loan of state personnel and equipment. Unofficial agencies may participate in financing a program on a demonstration basis. Frequently, the "know how" in public health is essential in the starting of a new program and those with previous experience may be loaned to assist the local community in the inauguration of a new activity.

5. Provide financial assistance. The benefits of public health activities are not on the individual community basis, and provision must be made for the equitable distribution of the cost of public health work.

6. Do basic and applied research. The inception of new progress requires a trial and error period. This might best be confined to one or a few areas, and, when techniques and procedures are developed, these can be given to other communities with reasonable assumption that there will be considerable saving in time, effort, and money.

7. Coöperate with other agencies, both public and private. Health, both from the individual and community standpoints, results from the coöperative efforts of many official and unofficial agencies.

8. Develop and carry on extensive health education activities.

9. Obtain laws and prepare regulations that will permit the establishment and increase the effectiveness of local health services.

10. Analyze and evaluate public health programs to determine their effectiveness, achievements, and the attitude of the people toward them. This analysis should preferably be done annually. Frequently, it is advisable to have such analysis and evaluation performed by someone outside of the department concerned. For instance, the analysis and evaluation of a county health department might well be performed by members of the state health department. Self-analysis and evaluation is likewise important, and each administrator should make such analysis of his own activities and adjust his program accordingly.

These objectives and techniques are as applicable to public health work in Texas, California, or any other state as they are to public health in New York State.

Allocation of Funds to Local Programs

G. F. MOENCH, OAK RIDGE, TENN.

The subject, "Allocation of Funds to Local Programs," is assumed to apply to the adequate financing and support for the extension of local health units for the nation.

It is also assumed that patterns, methods, and formulae are available. Funds are now currently available; therefore, this discussion deals with some dangers and offers suggestions for an action program relative to responsibility of the three potential sources of funds: local, state, and federal.

The financing of local health units began with an effort by the local community and has remained largely a local responsibility. In the last twenty years, certain state governments have made feeble attempts to assist local communities in the financing of local health departments. And, today, several states are doing an admirable job helping local communities.

The principle of federal assistance to states is well established. Modest sums have been provided and earmarked to deal with special health problems, such as venereal disease, tuberculosis, nutrition, and cancer control. Relatively little of this money has filtered down to the local health units development. It is high time that professionally trained people in public health unite their efforts to support a fundamentally sound plan for adequately financing local health units. Responsibility is at least half that of the local community in accordance with local financial resources, and the state and federal government must step in where the local level reaches the end of its ability to pay. Health services, both preventive and curative, cost money and are worth paying for. The need is pressing. Fast moving events of

this Atomic Age demand that we change the tempo of our thinking and movements.

There are three sources of danger, or factors to consider, in efforts to allocate funds and support to local health units: (1) Professional conventions and conferences have admirably discussed organization problems, including finance. For five years, these meetings have closed with no definite action. (2) Public health-trained people are conditioned to the belief that the growth and development of a local health unit is a long, slow process. In the light of present-day needs and knowledge, this dull, inert, negative, defeatist, smugly complacent attitude is a serious threat to the security of our nation. (3) The increased responsibility for new programs, the constant insecurity, the frustrating effect of heavy case loads on limited staff, leaves little time for constructive planning and adequate financing on a long-range basis. If we are to convince the consumer public that health services are valuable to the community, local health workers must believe wholeheartedly in health service goals and show by administrative action that public health cannot be compromised, neglected, shortchanged, or curtailed.

Several specific suggestions for overcoming some of our difficulties in allocating support of local health service units are offered for consideration.

First, public health workers must maintain within themselves the firm conviction that the principles of the entire program are essential, sound, and worth upholding against all odds. Ask the questions, "Do we really believe in the concepts of health practice that we are trying to instill in the consumer public?"

If so, are we functioning or working half as well as we know how? If not, what can we do ourselves to fit ourselves better to the job at hand?"

The second suggestion is the need for professional health administrators' association on a state-wide basis.

The third suggestion is coöperation with other professional and lay leadership by the organization of local health committees or councils. Many suggestions and patterns for this type of local health council are available from such organizations as the National Health Council, the American Medical Association, the National Congress of Parents and Teachers, as well as educational organizations.

The fourth essential is closer coöperation with voluntary and lay organizations as a means of interpreting financial needs and obtaining legislative support for the extension of local health units. Nearly every organization in the country has a health committee, a health interest, or a health program, and it is a responsibility of the local health unit to know just how the program can be integrated with that of the local health department to prevent an overlapping of services and wasting of resources.

The fifth specific suggestion is awareness of pending legislation, studying it as to objectives and source of introduction and support, following through with action to back it if favorable to community health services, and fighting it just as hard if it appears to be a threat to the health and welfare of the local community.

A most significant piece of federal legislation, which has a direct bearing on providing financial assistance from the

federal government to state health departments for support and extension of local health units for the nation, has been introduced into our Congress this year. This is the first time in history that federal aid bills have ever been introduced solely for the purpose of extending local health units. This bill is identified in the Senate as S-2189 and in the House as Joint bills H.R. 5644 and 5678, and is known as the Local Health Services Act of 1948. This legislation is initiated and sponsored by the National Congress of Parents and Teachers. Over forty-five other national professional, voluntary, and lay organizations, support the National Congress of Parents and Teachers in their introduction of the bill into the Congress of the United States of America.

It is suggested that each local health officer, and all others interested, immediately contact their state health officer and coöperate with him and the state and local Parent Teachers Association to follow the bill through its various steps to becoming a law, and to initiate local action and support at the proper time that will inform Congressional, Senate, and House committees of the needs for immediate passage of this legislation.

The need for favorable action on this bill is unquestionable. Regardless of how good the professional help and guidance in technical matters may be, there is a time when the assistance of lay consumer groups is essential. Consumers are voters and voters have a responsibility to inform their senators and representatives as to their wishes regarding health legislation.

Let us all go into action.

Amalgamation of Health Departments in Seattle and King County

EMIL E. PALMQUIST

The amalgamation of the administration and the combining of the clinics and the laboratories of the City of Seattle and of the King County Health Departments became effective September 8, 1947.

The idea of amalgamation in our state is not a new one since several of the first class and second class cities, some of them for many years, have pooled their resources with those of their respective counties to form districts or health units. Seattle, however, is the first large city (over 100,000 population) to begin such an amalgamation. A merger of the City and County Health Departments was first recommended in the book *Local Health Units for the Nation*. The impetus for the present amalgamation began in May, 1947, when the Health Officer of King County resigned with the recommendation that such an amalgamation be effected. The Board of Commissioners of King County requested recommendations from the King County Medical Society, which appointed a special committee consisting of three of its members, who after investigation recommended to the Board that they approach the City of Seattle and request consideration of an amalgamation of the City and County Health Departments. The Seattle Municipal League also made a study of the problem and approved the plan and recommended to both the city and county governments that they get together and work out a plan of amalgamation as far as possible under existing laws. The state at present has no enabling legislation providing for combined health units for cities over 100,000 popu-

lation. On the other hand, there are no state laws making it illegal to work out a combination by agreement. The existing law covering smaller cities and counties was passed as recently as 1945 after several of the cities and counties in the state had been operating on a combined health unit basis for many years. There was a precedent, therefore, with which we had to work.

Since there is no law setting up a way of merging the two departments, it was agreed that the amalgamation would be worked out on the following basis:

The Director of Public Health for the City of Seattle was made Director for both the City and the County Health Departments.

The Division Directors of the following respective divisions of the City Health Department were put in charge of the same respective programs for the County Health Department:

- a. Acute Communicable Disease Control (Epidemiologist)
- b. Division of Tuberculosis Control
- c. Division of Venereal Disease Control
- d. Division of Maternal and Child Health Services
- e. Division of Public Health Nursing
- f. Division of Central Administration, which includes the Director's office combined with the Chief Clerk and his staff
- g. Director of Laboratories
- h. Public Health Education
- i. The Divisions of Sanitation of the City and County are kept on a separate basis, each with its own chief under the general direction of the Director of Public Health. They will be combined under the same administration at a later date.

The Division of Costs for the jointly employed people who are the administrative personnel indicated above, was

worked out according to the population ratio of 75 per cent for the City of Seattle and 25 per cent for King County. The population in the City being 470,000 and the population in King County outside of the City, being 155,000. Actually, what has taken place is the joint employment by the City and the County of the same people to carry out the administrative work and then on an agreement basis combining the clinics, leaving it up to the discretion of the Director of Public Health to use to the best advantage the available space of both departments and the assignment of the employees.

Enabling state legislation, now being prepared, is still needed to effect a complete merger. Many factors must be considered, among which are: that the city employees have civil service and retirement benefits, and the county employees do not; a plan for permitting a single budget and the pooling and disbursement of moneys from a single fund.

The above is a successful beginning. The amalgamation has removed much of the confusion, overlapping, and duplication which existed before, and is proving beneficial to both the City and the County.

Health Coördination in New Orleans

JOHN M. WHITNEY

In August, 1947, the Mayor of New Orleans decided that the city needed a cleanup campaign. He called in the Health Officer who first suggested that a citizens' committee be appointed, but at the same time recommended that some type of permanent organization be effected which would mobilize and utilize citizen participation in various health activities each year. Since there was a very effective organization of block leaders during the late war it was felt that a start could be made by reactivating this organization. Accordingly the war-time leader of the block organization, a prominent civic minded volunteer, was called in and she agreed to accept the job of securing the active participation of as many of the former block leaders as would respond. However, she was willing to do this only on the condition that a permanent organization be set up with funds available to provide office and clerical facilities as well as educational supplies. Neither she nor the Health Officer wanted to engage in the

stereotyped "annual cleanup" and then see the city lapse into the same old condition. It was further felt that the time and effort necessary to enlist wide citizen participation would not be justifiable for just a single project.

The Council of Social Agencies in New Orleans has a Health Division which includes the voluntary health agencies, and the professional groups, as well as the official health agency. This division has functioned as a health council in the accepted definition of such councils as a planning and coördinating group for community health. In addition, there is in the Council of Social Agencies a "Community Volunteer Service" whose function is to recruit volunteer workers for such organizations as hospitals, Red Cross programs, etc.

After much discussion and many conferences a "steering committee" was set up consisting of the Secretary of the Health Division of the Council of Social Agencies, representatives from each

of the nine voluntary agencies operating in the health field,* from the Association of Commerce, the Young Men's Business Club, the Junior Chamber of Commerce, the public and parochial school systems; the block system leader, the director of the Community Volunteer Service, and the Health Officer.

The city administration came through with a \$10,000 appropriation to the health department to implement the entire program. A coördinator with clerical assistance was employed and housed in the health department. This coördinator's job was to secure health chairmen from every woman's organization in town and to arrange for meetings with these chairmen, first to explain the purpose and planned functions of the "Health Council of New Orleans" (as it was then named), and then to funnel information and materials through the chairmen to their members. The chief purpose was to get approximately 100 groups working on the same program at the same time. Practically every one of these groups had health committees and was engaged at some time during the year in its own pet projects. It was thought that many projects of community-wide significance could be put into operation much more effectively by having everybody doing the same thing at the same time. The city clean-up campaign served as the first example, and was a "natural" because a hurricane descended on New Orleans at about this time (September, 1947), and there we had a most effective stimulus.

Since the purpose of this report is not to give an account of the activities of the Health Council, suffice it to say

that the clean-up campaign was accomplished by intensive publicity, with actual operations by both city crews and volunteers during a one month period.

The next thing we had to consider was how to keep alive the interest and active participation of all the groups concerned. It soon became apparent that there was considerable duplication by the Health Council with the Health Division of the Council of Social Agencies with respect to planning, and with the Community Volunteer Service in respect to direct services. Also, from the administrative viewpoint of the Health Officer, here was this "coördinator" and her staff standing out like a branch on the department and spending funds officially appropriated to the Health Department. Further, the Health Division of the Council of Social Agencies was justifiably disturbed over the developing situation. On the one hand the Health Council was composed of a much broader representation than the Health Division would ever have, such as women's civic clubs, auxiliaries, veterans' groups, church societies, etc. In addition, the Health Council program was designed to be one of direct services, such as actual distribution by group members of literature, rat poison, or any other service relating to a community-wide program. On the other hand, many of the women's groups in the Health Council were also a part of the Community Volunteer Service. But the direct services they were performing were limited to a few central points such as clinics and hospitals, and in addition did not include educational programs. So it was felt that there was a definite need for the services to be rendered by the Health Council, and the problem now was how to furnish these services without duplicating and overlapping the areas of operation of the Health Division of the Community Volunteer Service of the Council of Social Agencies.

We have proceeded to effect this re-

Crippled Children Society
Social Hygiene Association

organization by placing the paid staff of the Health Council in the division of health education of the Health Department. The name will be changed to some title such as "Citizens' Health Committee." An executive committee will be set up with representation from the professional societies, the voluntary agencies, and the official agency. To the Health Division of the Council of Social Agencies will still be reserved the planning and coördination of all community health, and it will act as an advisory committee to this executive committee. All organized groups, including the Community Volunteer Service, will then carry out the programs and policies as

determined by the executive committee with advice from the Health Division of the Council of Social Agencies.

The Citizens' Health Committee will be considered more as an organization to supplement official work of the Health Department in special programs.

During the period of reorganization two additional projects have been successfully carried out—food conservation in January, 1948, and a city-wide rat poisoning campaign in April, 1948. Other contemplated projects are chest x-rays on a city-wide basis, annual physical examinations, and any timely health programs projected on a national basis.

What's Happening to Malaria in the U.S.A.?

JUSTIN M. ANDREWS, Sc.D., F.A.P.H.A.

*Scientist Director, Deputy Officer in Charge, Communicable Disease Center,
U. S. Public Health Service, Atlanta, Ga.*

THE general decline of malaria in this country is believed to have begun during the last quarter of the 19th century,¹⁻³ some years before it was known how the disease is transmitted. At that time, malaria virtually blanketed the eastern two-thirds of the nation, except for the Appalachian highlands, and extended up the Central Valley of California.⁴ Its retreat has been interrupted, at least during the latter half of the intervening period, by resurgences in prevalence at such regular intervals that a 5 to 7 year cyclicity in epidemic manifestations has been postulated.^{4, 5} The last of these periods of enhanced transmission took place during the mid-1930's of this century. By that time, the principal areas of endemicity had contracted to the coastal plains and lime-sink sections of the southeastern states and the flood-plain areas of the lower Mississippi and its main tributaries. Since this last upswing, 12 to 14 years ago, reported malaria prevalence in the U.S.A. has decreased steadily as shown in the accompanying graphs (Figure 1). Making generous allowance for the traditional errors of omission and commission in malaria reporting, it is evident that consistent declines in recorded morbidity and mortality, unprecedented in their magnitude and

duration, have been in effect for the last decade or more. This downward trend is verified by the general testimony of residents and by special field studies^{6, 7} in areas where malaria has been highly endemic in the past.

What is the significance of this latest recession? Since 1935 there has been no reported increase in indigenous malaria case or death rates in the country as a whole. This indicates that the regular wave-like pattern of malaria epidemicity throughout the nation is not an immutable phenomenon. If the negative slope of the last 12 years' experience can be continued or accelerated, it can mean nothing more or less than the ultimate extinction of malaria in the United States. To exploit this trend, it is important to determine its causes, if possible, while they are still in effect.

Is malaria being treated out of existence? Has it stopped relapsing or has man become generally refractory to infection? Have infectible anophelines become so few that transmission is not possible? Have these species lost their susceptibility to plasmodial parasitism?—or their taste for human blood? Have all rural homes in the South been made secure against insects?—and do their occupants remain indoors after dark so punctiliously that they are no longer accessible to mosquitoes? A brief review of these and other possible nullifying influences seems desirable (1) to

* Presented before the Georgia Public Health Association, June 10, 1947, and the American Society of Tropical Medicine and the National Malaria Society in Atlanta, Georgia, December 4, 1947.

Figure 2—Per capita income payments, by years, in the continental United States and in eleven southeastern states (Alabama, Mississippi, Arkansas, Florida, Georgia, Kentucky, Louisiana, Tennessee, Virginia, North Carolina, South Carolina, Tennessee, Virginia).

assess the evidence for or against their causal participation in the current malaria regression, (2) to judge the extent, if any, to which these phenomena may be due to purposeful control efforts, and (3) whether it would be wiser, in view of the present low level of malaria incidence, to stop all organized attempts at further malaria prevention as unjustified expenditures, or to continue them with the hope and expectation that, within the foreseeable future, they will result in the total eradication of the disease.

Economic improvement in the South

—The South shared in the nation's present wave of prosperity which started its upward swing (see Figure 2) at about the time malaria rates commenced their latest descent. In connection with this circumstance, it is pertinent to note that socio-economic progress was believed to be the prime determinant in the extinction of malaria in the Upper Mississippi Valley by various authorities,¹⁻⁵ though they disagreed as to the most probable means by which it was achieved. Malaria is more firmly entrenched by environmental conditions in the South than it was in the North, nevertheless it seems probable that economic improvement is the basis for various pressures to which it is now yielding. Those which may be presumed to exert antimalarial influence include better housing, more medical and public health services, more drainage for agricultural and suburban development, enlarged use of insecticides in homes, enhanced animal husbandry, and increased industrialization with its attendant shift in population residence from rural areas to or near metropolitan centers. Wartime and post-war shortages of materials and professional personnel have doubtless prevented the fullest elaboration of these forces against malaria.

Human susceptibility—Considering first the human factors which may have

been involved in the present recession, there appears to be little reason for assuming that it is due to an American loss of susceptibility to initial infection or relapse. Well over a half million American soldiers and sailors,⁸ including many from the South, acquired malaria overseas from 1942 to 1945, inclusive, evidencing no resistance to the numerous strains of plasmodia encountered. Some of the tertian infections imported subsequently are still relapsing after three years. Paretics and other recipients of induced malaria in this country appear to accept and react to blood- or mosquito-transmitted infections with old or new strains of parasites in recent years as their predecessors did before them, according to observers whose investigations involve the extensive use of this procedure.⁹⁻¹²

Antimalarial medication—It is difficult to assess correctly the role of medication in the malaria decline. Since the days of "Sappington's Anti-Fever Pills," residents of endemic areas in the United States have consumed huge quantities of ethical and proprietary antimalarials with the object of treating or preventing malaria. It seems logical to expect that drugs which reduce parasite densities in man should diminish his infectiousness to mosquitoes at the same time, but this effect has not always been sufficiently realized to be of significance in the prevention of malaria.

Thus, while the world thankfully accords memorable prominence in medical history to quinine for the relief it has given to countless millions suffering from malaria, it is now well known that the drug possesses no prophylactic properties, except the ability to effect the temporary suppression of symptoms, nor can it be depended upon to extinguish completely any type of malaria infection. Therefore, it is doubtful if quinine interferes perceptibly with the transmission of the disease. Certainly there appears to be no reason for be-

lieving that it contributed any more to the control of malaria in the South since 1935 than before that date.*

Quinacrine hydrochloride (atabrine) was introduced into general use in the South during the middle and latter years of the decade when the present malaria recession was just getting under way. Its early experimental application as a mass therapeutic and prophylactic among predominantly Negro populations with almost exclusively falciparum malaria was associated with encouraging reductions in spleen, parasite, morbidity and mortality rates.¹⁴⁻¹⁶ Later observations in Panama,¹⁷ led to the conclusions that atabrine was no more dependable than quinine for malaria control purposes when used in treating parasite positives discovered at monthly blood surveys. Critical tests^{18, 19} and general experience in malarious areas during World War II concurred in establishing that this drug, while not much more effective than quinine against vivax and quartan malaria, is virtually a specific against falciparum infection, its use in therapeutic or suppressive dosages resulting in a high percentage of non-relapsing cures of this and no other type of malaria. This unique characteristic plus the temporal association of atabrine and the recent malaria decline qualifies atabrine medication as one of the possible causes of the recession, without defining its actual importance.†

Population migration out of rural areas—Since 1935, there has been a notable migration from rural to urban surroundings throughout the United

States. This was most marked during the first half of the present decade due, presumably, to military induction and to the attractions of higher wages and better living conditions in and near the more populous centers where materials and equipment for Defense and War Industries Programs were being fabricated.

From 1917 to 1940, there was small but steadily increasing progress in the industrialization of the South as northern manufacturers shifted their factories to take advantage of more favorable labor conditions below the Mason-Dixon Line. From July, 1940 to May, 1944, the South received 24.4 per cent of the \$14,000,000,000 authorized by the War Production Board for manufacturing plants and equipment; this does not include the cost of plants whose post-war conversion to peacetime industry is doubtful.²⁰ During the same period, considerable numbers of Negroes travelled to the northern states to escape the effects of a waning cotton economy and with the hope of finding more productive and congenial surroundings.²¹

In many sections of the southeastern quadrant of this country, these events have resulted in transferring people *out* of rural areas where they might have had malaria and *into* urban situations where the chances of acquiring it were negligible. The total extent to which this phenomenon has taken place is not known at present, but some idea of its trend is conveyed by the upper curve in Figure 3, which indicates the progressive reduction in farm populations in the South Central and South Atlantic states from 1935 to 1945, inclusive. Thus it seems probable that a considerable depletion in rural population

* According to Norman Taylor, Director, Cinchona Products Institute, Inc. (personal communication), this country, prior to 1939, used roughly four million ounces of quinine each year, the annual variation being within 10 per cent of this figure. Its consumption "over a period of years" did not increase with the population. There is no way of determining the actual proportion used as an antimalarial in the South but, on the basis of available distribution data, it was estimated at the Institute that about two million ounces were used for that purpose.

† Information regarding the distribution and consumption of atabrine in this country could not be obtained from its principal manufacturer as the output of this product for the last six years has been controlled largely by the Army, Navy, and Public Health Service, and has been subject to use abroad as well as in the United States.

FIGURE 3—Estimated farm populations and numbers of all cattle in the South Atlantic and South Central United States, 1930-1946, inclusive.

has occurred. This may have assisted materially in malaria reduction in the last five or six years.

Anopheline susceptibility—Consideration must also be given to the possibility that changes in anopheline populations may have interfered with the transmission of malaria. Among such hypothetical factors, reduction in mosquito susceptibility to plasmodial parasitism due, perhaps, to environmental or cosmic influences would be of paramount significance if demonstrable. Such a phenomenon might be reasonably expected to manifest itself in insectary-reared as well as wild strains of mosquitoes. There is no published evidence to that effect with reference to the principal transmitting species in this country. Induced malaria for therapeutic and experimental purposes appears to have been transferred from

one person to another by means of mosquitoes with comparable degrees of regularity throughout and prior to the period under consideration.⁹⁻¹² While most of the naturally induced malaria has been transmitted with the Boyd strain of *A. quadrimaculatus*, established in 1932,²² other insectary stocks have been used and wild strains of this species have been brought into laboratories and their infectibility proved.^{12, 23, 24} Furthermore, it was shown in 1947 that native cases of falciparum and quartan malaria in South Carolinian Negroes, with or without symptoms, were readily infective to insectary-reared and wild-caught *Anopheles quadrimaculatus*, even though gametocyte densities were very low in some instances.¹³

Antilarval measures—Has the abundance of this transmitter diminished

sufficiently during the last twelve years to account for the malaria reduction observed? During this period, efforts of considerable magnitude have been made by federal, state, and local health agencies, and by private interests aimed at reducing anopheline densities, both on a community-wide basis and within homes. Entomological evidence of success as a result of these endeavors is limited; their probable effectiveness must be inferred largely from the nature and scope of their physical accomplishments.

The U. S. Army's continental experience with malaria during World War I was severe enough (see Figure 4) to require environmental control measures around southern cantonments. These activities had to be financed jointly from federal and local resources, thus directing attention to the fact that local governments were unable to bear the costs of malaria control operations which, as then conceived, were mainly antilarval.

Thus, during the depression years which followed, federal relief organizations (Civil Works Administration and Federal Emergency Relief Administration established in 1933, and the Works Progress Administration in 1935) were called upon to supply man power for malaria control purposes. They completed a tremendous amount of drainage in 16 southeastern states. The exact total is uncertain as existing reports of accomplishment^{4, 25} are not in agreement, but from them it appears probable that something in the neighborhood of 32,000 miles of "average-size" ditches were constructed draining 623,000 watered acres. Most of them were dug by hand labor—machine and dynamite excavation accounting for only a minor percentage—and a few hundred miles of the ditches were paved with concrete.

From the standpoint of good malaria control practice, these projects had serious faults. In the fulfillment of relief objectives, operations could be

FIGURE 4—Malaria admissions per thousand men per year for the U. S. Army in the Continental United States during World Wars I and II. Note the reduced military malaria experience in this country during the last World War.

MALARIA ADMISSIONS PER THOUSAND MEN PER YEAR FOR THE ARMY
IN THE CONTINENTAL UNITED STATES. WORLD WAR I—WORLD WAR II.

carried out (1) where and only for as long as the numbers of locally unemployed were large enough so that crews could be manned for malaria control drainage as well as for other relief labor projects desired by the community, and (2) where locally provided materials and equipment were available for matching against federal funds. These conditions tended to concentrate malaria control drainage projects in the more populous and wealthy counties, not necessarily the more malarious ones. Justification for locating work units was frequently based on nothing more than lay testimony of past malariousness. Drainage construction was restricted to new works, which meant that existing drainage-ways could not be maintained or improved with relief labor nor could it be used to keep in serviceable condition the ditches which it dug originally. In many though not all instances, local governments have provided for the maintenance of the drainage facilities.

As the Defense Program gathered momentum in 1941, national unemployment declined and many of the WPA Malaria Control Drainage Projects were discontinued except in the neighborhood of military training camps. During 1942, these were taken over by the U. S. Public Health Service and, together with other environmental malaria control operations around areas of military or war industries significance, were continued during the war years as a coöperative works program of the federal and various state health services concerned. Their efforts were coördinated by the Office of Malaria Control in War Areas, headquartered in Atlanta, Ga.

During the period of maximal military training and industrial production, malaria control drainage, filling, and larviciding were accomplished by this organization around approximately 2,200 localities of military concern in 19 different states. Through 1945,

these activities included clearing and cleaning, incidental to larviciding, of 37,000 watered acres and 96,700,000 linear feet of ditches; 5,700,000 gallons of oil and 73,000 pounds of Paris green were used in larviciding 660,486 acres; approximately 10,900,000 linear feet of drainage ditch of varying cross-section were dug (90 per cent of them by hand labor, 5 per cent with dynamite, 3 per cent by heavy machinery, while the other 2 per cent were lined or tiled ditches); mechanical and hydraulic fill amounted to 315,000 cubic yards.

This program was a great improvement over the preceding one from the standpoint of malariologic principle. Maintenance operations could be undertaken as readily as new construction. Local contributions were required only when adjuncts to drainage works such as concrete ditch-lining or culverts, tile, dynamite, etc., were desired. Early in the development of the War Areas Program, the policy was adopted of basing operations on potential malariousness, i.e., presence of infectible species of anophelines, rather than on lay testimony of previous malariousness. Entomologic evaluations were made throughout the progress of the program to check operational accomplishments. These have been summarized in Figure 5 and show (1) that malaria-carrying types of mosquitoes were less numerous within the zones where mosquito control activities, exclusively antilarval until the calendar year 1945, were carried on than in adjacent unprotected areas, and (2) that anopheline abundance in uncontrolled areas was certainly no less; probably more, in 1946 than in 1942 when enumerative observations were commenced. Spleen and parasite surveys were also made for evaluative purposes but were not very meaningful because of their lack of sensitivity in the face of decreasing malaria prevalence. Community health education and information programs

point of public health insignificance the malaria prevalence which existed when construction was begun. It is interesting to note that, due to a combination of uncontrollable circumstances in the early spring of 1945, anophelism in the lower two-thirds of the Valley reached the highest level recorded in twelve years, but without evidence of an accompanying increase in malaria prevalence.⁷

This incomplete catalog of federally stimulated efforts at reducing anopheline production is impressive but the effect of these endeavors on malaria prevalence is hard to appraise. Their application extends over the period of malaria decline, a fact which should neither hastily be dismissed as fortuitous nor taken for granted to have causal significance. That malaria reduction occurred near many of these operation sites as a result of breeding place destruction and antilarval measures is indisputable, but that these areas were sufficiently numerous, extensive, or malariogenically important to produce a coalescent malaria depression throughout the South is hardly credible. Furthermore, malaria has diminished to a greater or lesser degree in areas beyond the influence of the TVA and untouched by WPA or MCWA. Thus, it is evident that other factors in addition to interference with anopheline production have been concerned in this phenomenon.

Measures against adult anophelines—In spite of active educational efforts, demonstration projects,²⁷⁻²⁹ and higher incomes, the amount and quality of domestic insect-proofing has increased significantly in only a few of the rural sections of the South where it would

have its greatest effect as a malaria reductive measure.^{30, 31} Doubtless, this is due to the excessively high ratio of insect-proofing construction and maintenance costs to the value of poorer type houses.^{32, 33}

On the other hand, the use of domestic insecticides has increased prodigiously during the period under consideration. Data concerning the actual amounts packaged and sold are difficult to obtain as these are viewed by dealers as competitive information; however, certain regional distributors (serving the southeastern states) and national manufacturers were willing to disclose production trends in terms of annual percentage increase. According to the estimates of the former, the distribution of these products, commencing with 1931, increased each year by amounts which varied with different concerns from 20 to 40 per cent until 1943, when output was crippled by lack of metal for containers and handsprayers. Compounded at the annual rate of 20 per cent, this would represent an overall increase of nearly 7½ times for this period.

One national producer wrote that the volume of his company's household insecticide distribution in the southeastern states increased 1,404 per cent from 1935 to 1945, but he believes that this was due to the energetic advertising of his concern and that competitive business did not advance to that extent. However, one of his principal competitors supplies the following indices expressing in terms of percentage relationships, based on business done in 1939, the amounts of domestic insecticides distributed by his dealers in 13 southeastern states (figure for 1939 being taken as 100 per cent).

| Year | Per cent | Year | Per cent | Year | Per cent | Year | Per cent |
|------|----------|------|----------|------|----------|------|----------|
| 1931 | 20 | 1935 | 52 | 1939 | 100 | 1943 | 160 |
| 1932 | 27 | 1936 | 64 | 1940 | 85 | 1944 | 139 |
| 1933 | 32 | 1937 | 75 | 1941 | 89 | 1945 | 140 |
| 1934 | 42 | 1938 | 79 | 1942 | 147 | 1946 | 56 |

This manufacturer is of the opinion that the sharp decrease in sales volume during 1946 was due to the large amount of "free" spraying which was done by local and federal government agencies during that year.

These indications, while remarkable, do not tell the whole story because numerous small operators commenced domestic insecticide production during this period, thus adding materially to the total made available to consumers. It is probably conservative to estimate that 10 to 20 times as much household insecticide was used in the southeast during the early war years as in 1931 to kill mosquitoes as well as other domestic insects.

In 1945, the Office of Malaria Control in War Areas embarked on its Extended Program of malaria control. This consisted of the application of residual DDT to the interior surfaces of homes and privies in counties where substantial mortality from malaria* had been reported during the period just before World War II. This was aimed at preventing the dissemination of malaria from home-coming veterans who had acquired infection overseas. From January 1, 1945, to September 27, 1947, nearly 3.2 million house-spraying applications were made in rural areas or small towns in 309 counties. The average number of sprayings per house varied from nearly two in 1945 to not quite one and one-half in 1947, when 875,534 different houses were treated.

Domestic insecticiding with residual chemicals such as DDT appears to be the most feasible single approach to malaria prevention now available in the South, considering the special problems of house construction, the distance be-

tween homes in rural sections, and the economy of the inhabitants. Most anopheline mosquitoes bite only at night and as more people are within their homes than elsewhere during the hours of darkness, it follows that measures which prevent mosquitoes from entering houses or which destroy the insects after they are inside are of transcendent importance in preventing malaria transmission. It is probable that the insecticidal applications, both ephemeral and residual, made within the home in the last 12 years have accomplished more than any other one measure to reduce malaria transmission in the South.

Anopheline deviation—Another circumstance which may have been of considerable assistance in reducing the domestic density of anophelines is the expansion of cattle raising in the southeastern states. The lower curve in Figure 3 shows the estimated cattle population in the South Atlantic and South Central states from 1930 to 1946. Cattle husbandry has increased in the South as cotton cultivation has receded in importance and as rural labor has migrated out of the region. Longer grazing seasons than are available elsewhere in the country, less labor requirements, accessibility to eastern markets, and better protective techniques now available against cattle diseases spread by biting arthropods are said to be factors contributing to this development. The presence of more cattle is believed to be important, malariologically, because *A. quadrimaculatus* has a strong preference for cattle blood.³¹ As these mosquitoes emerge from their breeding places and seek blood meals, they are less likely to enter human habitations in large numbers if they can satisfy their appetites more conveniently from cattle in the fields or in stables close to houses.

The trends of the two graphs in Figure 3 indicate that the decrease in

* In the calendar year 1946, counties were approved for Extended Program operation if the average annual malaria mortality rate during 1938 to 1942, inclusive, was 10 or more per 100,000 population. In 1947, the base was broadened to include rates down to 5 per 100,000. Counties with evidence of current malaria morbidity were included both years.

the farm population of the South occurred while the cattle population was on the increase. This suggests that the antimalarial influence of these two circumstances may have been compounded by their contemporaneous development.

DISCUSSION AND SUMMARY

Until medical and public health practices in the reporting of malaria cases and deaths are improved to the point of being more dependable measures of the actual morbidity and mortality due to this disease, certain reservations must be entertained concerning its real status and shifts in prevalence. It does appear to be diminishing, however, and on the basis of the foregoing, the following tentative deductions seem to be justified. Certain of these, derived from information collected over broad regional expanses, deserve more searching and precise investigation in restricted study areas to determine the nature and extent of their local impact on the incidence of malaria.

It appears that there has been no essential deterioration in the potentialities of the parasite-host-vector system of malaria transmission in the United States during the last twelve years. The infectivity of the various species of *Plasmodium* capable of parasitizing man and transmitting mosquito remains unimpaired. It seems more likely, therefore, that the malaria recession can be explained in terms of quantitative rather than qualitative changes.

The widespread efforts at areal reduction of anophelism in the South by antilarval measures have depressed and possibly extinguished malaria endemicity in certain localities, but it is doubtful that these programs were primarily responsible for the regional decrease. The reduction of *domestic* densities of anophelines by the use of insecticides, as a result of deviation by cattle, and to a lesser extent by insect-proofing of houses is held to be a more important

and uniformly extensive causal factor.

Other circumstances contributing to the general decline are (1) population movements from rural areas in the South where malaria could be acquired, to urban centers in the South or to other parts of the country where malaria does not occur, and (2) improved anti-malaria medication.

Economic advance has undoubtedly stimulated the development of most of these factors. A depression might be expected to send people out of the cities back to the country where unimproved housing would quickly deteriorate in the absence of maintenance. Money would not be spent for household insecticides and the most effective anti-malarials. Under such conditions, malaria could again become a public health hazard of great prominence.

If malaria can be eradicated in this country and its reintroduction prevented or controlled—and this possibility is viewed as reasonable^{8, 37, 40} economic depressions could have no malariogenic effect. Malaria prevalence and transmission have reached new lows. Control techniques are more effective today than ever before, though doubtless their efficiency can be still further improved. These considerations constitute compelling motives for taking advantage of our present strong position. They offer a challenge to national, state, and local health agencies to combine in effecting the complete annihilation of the "world's greatest scourge"³⁸ in the United States.

Some Labor Union Enterprises in Public Health Economics

B. A. KOGAN, M.D., DR.P.H.

*Director of Maternal and Child Health, Department of Public Health,
Oakland, Calif.*

PUBLIC health is medical sociology. The broad scope and numerous tools of its practice necessitate specialization. Recently, and belatedly, an old specialty in the field has been newly defined as public health economics. Its rudiments, though inherent in social organization, have until recently been inadequately studied.

Mutual sickness and death benefits were not unknown among the ancient Hebrews, Greeks, and Romans. Many medieval guilds, despite primary religious or economic purposes, included provisions for such benefits in their charters. These primitive efforts were plagued with insolvency. In 1793, however, England saw the first legal restrictions designed to create financial security in friendly societies. More than a century of experience followed during which considerable opposition to increasing government interference developed; the National Insurance Act of 1911, an expression of majority rule, temporarily settled the argument. In this country the course of labor has been altered by basic differences in public health economic history; not the least important of these was the opposition of Samuel Gompers to any form of national health insurance. His social philosophy, in this respect, is essentially comparable to that of Senator Taft. By the mid-thirties, several great American unions were paying old age, death, disability, sick, and other benefits which had de-

veloped fortuitously and were frequently inadequate.

Space does not permit complete discussion of historical factors. The purpose here is to consider some recent efforts made by certain American labor organizations in redistributing the cost and thereby sharing the economic risk of sickness.

The First UAW Medical Research Institute—In June, 1937, an undue incidence of lead poisoning among auto workers, a desire to provide medical care for strikers, and interest in promoting both an industrial health education program and an industrial disease law led the UAW-CIO to open a Medical Research Institute. The purpose was research in the field of occupational disease. Collected data, obtained through worker and plant examinations, were to be used in formulating demands for better working conditions from management and government. Members, suspected of having an occupational disease, were to be referred to the Institute by shop stewards and union committeemen. Therapy and legal medicine were, initially, specifically omitted from the program; the latter limitation was, however, obviated by a new industrial disease law. Union physicians helped members to meet the medicolegal talent of the companies but their major interest lay in the concept that union support of an industrial disease law prompted installation of pro-

TECTIVE devices which would reduce industrial disease and injury. Patients requiring treatment were given the names of two physicians from a list supplied by the Wayne County Medical Society.

In 1938, in the midst of a growing program, during which thousands of men were examined and industrial disease and accidents decreased spectacularly, the Institute was discontinued. Unstable financing and lack of intra-union harmony were the causes. Specifically: (1) the financial responsibility for the Institute could not be settled; (2) the Institute had opened just after the union had increased membership from 25,000 to 300,000 and had collected \$327,000 in initiation fees. The layoffs, strikes, and lockouts of 1937 and 1938 decreased collectable union dues despite an increasing membership; (3) the union tended to concentrate available moneys on the Ford organizing drive; (4) the UAW split into UAW-CIO and UAW-AFL factions which resulted in the tying-up, by court order, of all Institute equipment. It took almost two years for the courts to decide which faction had title to the property.

The Second Health Institute of the UAW-CIO—In 1943, in accordance with previous convention resolutions, the UAW-CIO Health Institute was reopened and is now supported by (a) per capita assessments of over 350,000 members, (b) community chest donations, and (c) international subsidies. In its present quarters (the former home of the Edsel Ford family) are offered medical diagnosis by general practitioners and specialists, health education, and personal services. Many interested agencies, such as universities and the Detroit Health Department, are coordinated in the program.

The diagnosticians, using union technical services, such as routine blood and urine examinations, E.K.G., B.M.R., and x-ray are not only able to cut the

expense of diagnosis for a patient but also provide the advantage of earlier diagnosis. Patients are referred elsewhere for treatment; the Wayne County Medical Society assists in this. The most common diagnosis is psychoneurosis; such members are referred to the Personal Service (social case work) division for assistance. Between July, 1946, and June, 1947, only 12.6 per cent of patient visits were related to industrial disease or injury.

The Personal Service Department is occupied with the multiple ramifications of social case work. Vocational rehabilitation, psychiatric referrals, assistance in mental hygiene, coöperation with other referring or assisting agencies are but a few of the major duties of this staff of two trained social workers.

A remarkable health education program provides well attended classes taught by authorities. Health and Safety classes train local leaders to become foci of information for others. They know their machines; such education betters their bargaining position for healthful working conditions. Industrial Psychology is taught to improve intraunion and labor-management relationships. Consumer Health and Physical Education classes ("charm classes") attract female members and wives of male members. A Health and Human Relations course deals with emotional, sociological, and economic problems of women. Swimming and Health Education and Dancing and Health Education designate classes combining athletic activity with health lectures. This department is also responsible for exhibits, press releases, a monthly health pamphlet, mat service, and radio programs.

Member utilization of these services has increased tremendously in the past two years. It is idle to question the apparent values inherent in this public health economic enterprise. Despite obvious limitations (such as the absence

of a treatment program), it today surely justifies its existence. The permanence of the Institute must, however, be considered in the light of UAW-CIO support of a federal health bill, notorious intraunion disputes, and both labor and management threats to employment which inexorably curtail financial support of such ventures. The union has planned a hospital; but strikes cost money, and so do hospitals.

The Union Health Center of the International Ladies' Garment Workers Union—One consequence of a strike in 1910 was the selection of a Joint Board of Sanitary Control to study "sweat shops." The shocking conditions discovered by this group as well as by the U. S. Public Health Service resulted, in 1913, in the establishment of the Union Health Center. It flourished at first but, in the decade following 1922, intraunion disputes (culminating in the defeat of the communists), a catastrophic strike (1926) and the depression, all combined to jeopardize the Center. It was maintained largely because of the self-sacrifice of the idealistic personnel.

Weathering this adversity, the I.L.G. W.U. Health Center has, since the presidency of Dubinsky, grown enormously. A largely female (85 per cent) membership, seasonally employed and less demanding than men regarding wages, is appreciative of a convenient, sympathetic source of competent medical care, most of the cost of which is met by an employer payroll tax. Those few affiliates without prepayment medical services pay but \$1 per service.

This ambulatory clinic offers diagnostic and treatment services suited to the studied specific needs of the membership. In addition, it administers the medical aspects of the various local sickness insurance programs. There were, in 1946, nineteen different sick benefit and eight hospitalization plans; diverse cash benefits for surgery, maternity, convalescence, tuberculosis, and

eyeglasses were offered by a varying number of locals. Active health education, worker rehabilitation, and social work programs are in force. Despite the greatly expanded clinic space and services, there still remains the problem of meeting the ever growing utilization of the membership.

The reasons for this record are apparent. Aside from the advantages to the membership, one must point to the brilliant, often idealistic administration. Pure altruism cannot, however, be an objective criterion in evaluating the permanency of a public health economic enterprise. Moreover, the Dubinsky era of harmony is a personal victory, not reflective of the entire union history; the inevitable termination of his presidency might well be accompanied by familiar destructive discord. The comparatively attenuated basic problem of this union is collective bargaining for better wages, hours, and working conditions; the Center experience may well be used in promoting this function. However, the success of a union enterprise in public health economics can be at the mercy of all the vagaries of labor economics and politics. Social ventures can be a cohesive intraunion force; their stability is weakened in so far as they are a subsidiary, rather than a primary, union function. Finally one must question the stability of an employer payroll tax (gained during a business boom) in an economic depression.

The Dental Clinic of the Chicago Amalgamated Clothing Workers—The then Dean of the Northwestern University Dental School, in an interview in 1928, regarding the newly opened, well equipped and staffed ACW dental clinic, was quoted as follows in a union publication: "The Amalgamated Dental Clinic will serve not only the 25,000 members of the union, it will serve 100,000 because it will take care of the families of these members."

These high hopes failed to materialize.

Examination of overhead (salaries, dental equipment, laundry, magazines) and income (primarily collected from dental fees, sales of tooth paste, toothbrushes and dental floss) reveals that, from inception until mid-1945, the clinic operated under persistent financial deficits. Since competent service at reasonable fees, and not profit, is the primary purpose of the clinic, a strict financial judgment may seem unjust. However, operating losses and gains do provide a concept of the service utilization. By mid-1945 a total of 3,924 patients had been seen, an average of 230 yearly. Less than about 1 per cent of the eligible members and about 0.25 per cent of all eligibles had availed themselves of the service. From October, 1943, to July, 1945 (twenty months of acute dentist shortages), the salaried dentist saw 98 new patients, an average of 4.9 per cent monthly. The employed personnel had dwindled, by mid-1945, to an unassisted dentist; the laboratory was unused.

This public health economic enterprise has failed because (1) the union leadership has not adequately educated the membership regarding the service; (2) the hours and location of the centrally located clinic are inconvenient for the decentralized membership; (3) the fees are not comparably low enough to warrant sacrifice of the individual choice of a dentist; (4) adjustments in dental practice are unavoidably frequent; foci of dissatisfaction in general dental practice are usually lost in a large community; in union practice one patient's dissatisfaction may be spread to an entire local.

Why is the clinic maintained? It is a symbol of intraunion cohesion. In a letter dated July 18, 1945, the manager of the Chicago ACW wrote this writer:

"Our organization is not a business organization, nor is it looking for profit. We have other departments that are not financially sustaining themselves, as our cultural groups,

concerts, and educational work. All these departments are not profitable departments, but are essential . . . we feel that if we can give them the best services for a reasonable cost to whatever members are willing to avail themselves of it, we are protecting and servicing at least that many people with the knowledge that our organizational intentions are to give them more service."

The UAW-CIO and the Blue Cross Plan—The early success of the Michigan Blue Cross Plan is largely due to the UAW-CIO. Although the insurance agreement is between employer and insurance company, union-employer agreements have resulted in the enrollment of over 350,000 members from the Chrysler, General Motors, Packard Motors, Continental Motors, and Briggs companies alone. It is estimated that over 50 per cent of the total Michigan Blue Cross enrollment is comprised of about 225 UAW-CIO groups. The Group Hospitalization Report of February, 1941, by the UAW-CIO Chrysler Committee, in selecting the Blue Cross over the Aetna contract, illustrates the union capacity to override the express recommendation of the employer. The Fruehauf Trailer Company even experienced a strike because of its reluctance to discuss insurance plans with the union.

This vast free advertising agency is recognized by the Blue Cross directors. Five union men, employed by the insurance company, act as trusted advisers for the assured. Their position is analogous to that of union shop committeemen who are paid by industry but work for the union for the common good. The functions of the union member committee of the Blue Cross Plan are: (1) to assist in claim adjustments; (2) to act as an educational buffer between members and insurance company; (3) to present union grievances to the insurance executives; (4) to promote Blue Cross enrollment at local meetings.

These arrangements augment the familiar benefits of the Blue Cross con-

tracts. Of some interest is the disproportionately small union representation on the executive superstructure of the Michigan Blue Cross Plan. Of major importance, however, is the fundamental disagreement in public health economic philosophy between the insurance company and the union; the non-profit insurance company opposes a national health insurance act. These, and similar, employer-insurance company agreements are temporary union expedients. They bridge a gap; at the distant end of that gap is national health insurance.

The Insurance of the Ford Motor Company Employees—The Ford Motor Company was, in 1939, making two payroll deductions; one was for life, sickness and accident (Travelers Insurance Company); the other was for hospital and surgical coverage (Michigan Hospital Service and Michigan Medical Service). An irreconcilable dispute between the then anti-union motor company and the Michigan Medical Service ensued when the latter added a union official to the Board of Directors.

The motor company discontinued the Blue Cross insurance at the end of the contract year and transferred the risk to the Travelers Insurance Company. However, less than a year after the UAW-CIO obtained a closed shop contract they advised the company of their dissatisfaction with the health insurance management. The union was then promptly notified that, as of midnight February 28, 1942, the membership would be without company-sponsored health insurance.

It thus became the urgent business of the UAW-CIO to find comparable insurance for the Ford membership. The John Hancock Mutual Life Insurance Company signed a temporary emergency agreement with the International UAW-CIO assuming the terminating liabilities of the Travelers Insurance Company and obtaining an option on the new master contract effective on

March 28, 1942. This was the first master contract to be signed by a major mutual insurance company and a great union. The Ford Motor Company agreed to continue wage deductions.

The experience of even the first year revealed a low monthly ratio in the sickness and accident portion of the contract. By July 1, 1944, losses were persistent in the accident and sickness part of the contract and the premiums-claims difference in the hospitalization and surgical experience was uncomfortably small.

The factors which developed during the life of the contract (2+ years) that caused the loss ratio were: (1) the female percentage of the insured group increased from 11.8 per cent to 28 per cent. Females are a greater general risk in health insurance; specifically, furlough decisions to raise families resulted in an undue number of obstetrical claims; (2) the average age of the Ford employees increased from 37+ to 51+ years. Younger, healthy members of an insured group are expected to compensate for the greater risk encountered in the older age group. A considerable proportion of the insured group was composed of selective service rejects and medically discharged veterans. The young people were, moreover, transient, leaving the older age group behind to increase the risk; (3) Negro employees of the motor company, considered a poorer risk, increased from 9 per cent to 14.6 per cent; (4) the motor company qualified under the Workmen's Compensation Act as a self-insured risk. Many union leaders blamed the difficulty in differentiation between non-occupational (insurance company) risks and occupational (motor company) risks as a major factor in the poor experience.

The mutual insurance company could not, under Michigan Insurance law, penalize their other assured persons by continuing a yearly losing contract. Some union leaders, pointing to the legal acceptability of the life loss ratio, in-

sisted that a strict reading of the statute directed the insurance company to carry the risk. The insurance company, however, maintained that the policy holder, the International UAW-CIO, was the only legal source of added income. The International refused to bear losses involving less than one-tenth of the total membership. Not only were no dividends to be expected but the union, being tax free, could not write off its contribution as part of overhead cost.

The UAW-CIO enterprise was discontinued at the end of two years and three months, and it was assumed by the Ford Motor Company.

The Panel System of the Transport Workers Union—The Transport Workers Union, on May 15, 1939, organized a panel of general practitioners, one for each of thirty-five districts in Greater New York. Not only were they to meet demands of members for assistance in compensation cases but were also to initiate a needed health program. Three sources of financial support were established: (1) the International contributed 10 per cent of the cost and assisted in an emergency subsidy; (2) the compulsory purchase of \$1 tickets to a semi-annual dance sponsored by Local 100 provided some revenue; this plan was necessary because of the difficulty of assessment without a complicated referendum vote; (3) the Local contributed \$50,000 yearly and shared in an emergency subsidy.

A lay union "medical welfare committee" and a professional "staff advisory committee" governed the program. The professional group recommended appointments and procedures which were decided upon by the lay group. From the 600 applications, the 35 who were selected were paid 12 cents per capita per month to service approximately 1,000 members as follows:

1. An unrestricted number of office calls, during office hours, without charge.

2. An unrestricted number of home visits from 8:00 a.m. to 8:00 p.m. without charge.

3. Assistance in compensation cases; the fee for this was not set by the union.

4. Examination to determine physical fitness for jobs.

5. One yearly physical examination.

6. Referral to any of nine union appointed specialists who were paid a flat fee per case.

7. Superimposed fees could be charged for I.V. therapy (\$1.00); radiant energy treatments (\$.50); diathermy (\$1.00); B.M.R. determination (\$3.00); minor office surgery (\$2.00-\$4.00); complete obstetrical care (\$35.00).

The union, in addition, made arrangements for reduced prices for members with an optical house and drug stores.

Statistics show that the plan was well utilized. The few complaints, originating from the offer of an unrestricted amount of services, were settled by the governing boards. The physicians' paper work was limited and required but a few moments.

The discontinuance of the plan, after but a few years, was caused by two factors: (1) city purchase of the transport system invalidated the closed shop, reduced the membership, collectable dues, and available money for the plan; (2) the war decreased the number of physicians forced to practise idealism as a means of introduction into a community.

In purchasing labor (medical) from those under relative financial duress, the union violated its own philosophy; wage-hour standards proportionate to rendered services were not established. Physicians were obtaining community introductions and prestige by assuming poorly limited duties for about 1,000 members for about \$30 weekly. Little wonder the plan collapsed with the increased price of medical care which occurred with decreased supply and increased demand.

Present systems paying blanket fees per medical service are open to question. It is illogical to charge one fee for a 20 minute simple appendectomy, fol-

lowed by an uneventful convalescence, and the same fee for an 80 minute appendectomy, followed by a complicated convalescence involving considerable risk and labor. Job analysis and job qualification studies should receive as competent analysis in public health economics as they do in industry. It is time to evaluate the limitations of the opinionated meditation of those not adequately trained in either or both public health and/or economics. Public health (or medical) men ignorant of economics and economists ignorant of public health adumbrate the problem. Personnel should be trained to bring these interested individuals to a mutual understanding.

Further major criticisms of this plan are the insecure financial services, inadequate controls over quantities of superimposed fees for services, and absence of union-physician contracts.

The panel system of the International Workers Order has been more stable because this order is not so much bothered by union problems.

The Union Owned Insurance Companies of the Amalgamated Clothing Workers—A. In New York:

Collective bargaining agreements in 1942, 1944, and 1945, between the ACW and three major employer associations established weekly employer payments to three separately administered insurance funds of sums equal to 2 per cent of wages paid to members. Actuaries assist the union fund trustees and the employer advisory committee in determining what coverage to purchase from the created capital stock company, the Amalgamated Life Insurance Company, Inc. The trustees of the first Amalgamated Insurance Fund (1942) created the company with an original capital of \$300,000 (3,000 shares were purchased at \$100 par value) and surplus of \$150,000; both capital and surplus were by June, 1945, increased to \$1,-

000,000. The New York legislature in the 1942-1943 session legalized this novel insurance agreement. The state licensed the company, on September 23, 1943, to sell insurance to over 90,000 ACW members. The Equitable Life Insurance Company assumes the risk of about 13,000 employees in the 18 states, refusing to license this international union insurance company.

The company has proved financially stable and offers limited life, accident and health, hospitalization and maternity coverage.

B. In Chicago:

The Amalgamated Life and Health Insurance Company of Chicago was established April 1, 1940, with enormous reserves built with employee-employer contributions originally collected by the Amalgamated Social Benefits Association for unemployment insurance; unemployment insurance had been obviated by the Social Security Act. The Social Benefits Association purchased 2,000 shares of stock at \$100 par value and paid a premium for the stock providing a \$200,000 capital and a \$100,000 surplus for the insurance company. The company is thus a member-owned legal stock reserve life insurance company. The company charges the Association a definite rate, set by an actuary, for about 12,000 certificates for life, accident and health, and hospitalization. The money paid the company is independent of the amount collected, leaving the association with a surplus to be used for future purchases of extended benefits. The income and reserve of the association have grown tremendously since 1942. Similarly the insurance company surplus has increased yearly because the nonparticipating contract does not pay dividends on the policies. Obviously, the association need not increase its surplus with dividend collections; the dividend amounts remain in the company to increase its surplus and stability.

Both the association and the company are union governed. Experience of the company has been, to date, excellent and reflects intelligent actuarial planning.

Any evaluation of these plans must be dominated by the fact that (1) they have averted catastrophe for thousands of members. Other advantages may be listed: (2) the centrally located systems prevent loss or delay of benefits because of employee transfer from one local or employer to another; (3) profits accruing from good experience and management belong to one group which gains broader coverage at lower cost; the members do not pay for the losses of other groups; (4) ACW members receive more sympathetic consideration of claims; (5) this well managed, solvent company has reserves sufficient to withstand depression periods during which individual voluntary insurance might be cancelled; (6) adjustment policies exclude intermediate parties; (7) this plan demonstrates a high level of employer-employee coöperation; (8) the plan is a force for intraunion solidarity; (9) the operating cost, reduced by central administration, can be paid for by investment interests.

The ACW insurance plans have various shortcomings: (1) they are non-voluntary; (2) their certificates do not cover the family, which is the greatest problem in public health economics; (3) these income-tax-deductible employer contributions were granted during a business boom. A depression might, even-

tually, not only preclude further contributions but, as has happened, the employer might even have to seek loans from the union just to save a business in which to employ members; (4) neither the hospital nor medical professions are represented in the plans; (5) competent labor students hold that the ACW is playing conservatism for revolutionary ends; i.e., the ACW hopes that unionized workers will, in time, own and operate industry; (6) conversely, critics have labelled the plans as employers' paternalism, weakening union bargaining positions for better wages, hours, and working conditions; (7) in the Chicago plan, rapid piece workers pay a higher premium for the same benefits obtained by slower workers who contribute less.

CONCLUSIONS

Organized labor is woven into the very fabric of public health economics. Social ventures are, however, of secondary importance to leaders of organized labor. Their primary purpose is to meet a monopoly of capital with a monopoly of labor, and to use control of labor to gain further advantages in wages, hours, and working conditions. For this reason, despite Herculean and seemingly successful efforts, they can never meet the whole public health economic problem of their members.

They hope that a national health bill will, as in Britain, some day undertake the problem for the American laborer. They will vote for this hope.

International Population and Vital Statistics*

FORREST E. LINDER, PH.D., F.A.P.H.A.

Chief, Population and Vital Statistics Section, Statistical Office of the United Nations, Lake Success, N. Y.

PERHAPS the most outstanding fact about public health and vital statistics is that the interests of the workers in this field are related in a unique manner. Public health work is carried on through a chain of city, county, state, national, and international organizations. At each operational stage there is a need for factual data upon which to base program planning and evaluation. But there is one fact which gives public health statisticians a gratifying sense of community of interest. That is, effective work at any one stage contributes to, and, in turn, is dependent upon the work done at the other stages.

Consider for a moment some of the other statistical fields. Consider statistical work in the fields of agriculture, foreign trade, labor, finance, production, transportation, national income. Is there a single one of these in which the work of an international agency is dependent upon the work of a national agency, which in turn, is dependent upon a state agency, which is also dependent upon city and county work?

In reverse, this chain of dependency means that each unit within a state has an interest in the work of the state, national, and international offices. Each state has a legitimate concern and responsibility in relation to the problems

of national and international collection of data. Each national government has a heavy responsibility to partake in and contribute to those international activities which have the development of world-wide data as their goal.

There is no need to demonstrate here that public health planning should be based on accurate facts, and this is as true for the program planning of international organizations as for others.

The recognition of this need for international population and vital statistics is no new phenomenon. The long and fruitful work of the International Statistical Institute and the League of Nations in this field is proof that, especially in Europe, demographic facts have long been considered essential for international as well as national purposes. In more recent years the needs for demographic data have been strongly expressed among the American nations. The Eighth American Scientific Congress, the XI Pan American Sanitary Conference, the First Pan American Conference on Social Security, and the First Inter-American Demographic Congress are only some of the recent American conferences which adopted resolutions and recommendations calling for improved population and vital statistics.

In view of the ever increasing activities of the national and local governments in statistical work, and the constant efforts of various inter-governmental and professional societies in the

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

field of demographic statistics, it might be well to ask, what new influence or impetus can be added by the United Nations.

To those directly concerned with the compilation or use of vital statistics it is a source of satisfaction that the United Nations took early recognition of the importance of all types of statistics, and particularly of demographic statistics. The Statistical Commission was established with broad terms of reference relating to the collection, improvement, standardization, and dissemination of statistical data in all statistical fields including population and vital statistics. In addition to this, the Economic and Social Council, requiring advice and assistance in matters affecting or affected by population changes, established a Population Commission. This special commission for population is to arrange for studies and advise the council on population changes and policies, interrelationship of economic and social conditions and population trends, migration and other population problems.

Corresponding roughly to the interests of these two commissions there have been established in the United Nations Secretariat two units concerned with population matters. One of these is the Population and Vital Statistics Section of the Statistical Office. This section is concerned primarily with problems of collection, improvement, standardization, and distribution of data. The other unit, the Population Division of the Department of Social Affairs, has full responsibility for the analysis of population data and for its interpretation in economic and social terms.

In addition to these offices in the United Nations, several of the Specialized Agencies have interests in various aspects of population and vital statistics. While all of the Specialized Agencies have interests at least in population totals, the World Health Organization, the International Labour Organization,

and the Food and Agriculture Organization are concerned with more detailed health and demographic statistics.

The World Health Organization is not yet formally related to the United Nations as a Specialized Agency, and its future plans in this field are not yet fully developed. The scope of its present work consists primarily in a continuation of the statistical work of the Epidemiological Intelligence and Public Health Statistics Service of the League of Nations Health Organization, of the Office International d'Hygiène Publique, and of the Epidemiological Information Services of UNRRA.

It is obvious that the statistical needs and interest of WHO will be wide in scope and, in the same fields, closely related to the interests of the United Nations and other agencies. Their interests will certainly include morbidity, mortality, birth statistics, general health statistics, epidemiology, population, and other general statistics on conditions affecting health.

The WHO constitution authorizes establishment of statistical services and requires that "Each member shall provide statistical and epidemiological reports in a manner to be determined by the Health Assembly." The constitution gives the Health Assembly authority to adopt regulations concerning "recommendations with respect to diseases, causes of death, and public health practices."

The current statistical publication program of WHO consists of the *Weekly Epidemiological Record* which is mainly concerned with the incidence of the international quarantinable diseases; the *Monthly Epidemiological and Vital Statistics Report* which deals with all epidemic diseases and also births, deaths, and infant mortality. An *Annual Epidemiological Report* is also in preparation. These reports are continuations of earlier League of Nations series.

In addition to statistical information,

WHO is obviously concerned with many aspects of statistical technique and organization. An international Committee for the Preparation of the Sixth Decennial Revision of International Lists of Diseases and Causes of Death has been appointed and has drafted a tentative classification. The Statistical Office is represented on this committee by an observer and is coöperating with WHO in obtaining technical comments on the draft classification from national statistical offices. Presumably many other technical problems will also be considered by that organization. There is every reason to expect that the Statistical Office and WHO will continue coöperative efforts for the technical improvement of statistics in the fields in which both are interested.

Together, the offices within the United Nations and those of the Specialized Agencies, working in coöperation, form the most extensive international organization ever to be concerned with the problems of population and vital statistics.

The effective utilization of this international machinery as a new path of progress for demographic statistics depends upon a clarification and a sharpening of our concept of the kinds of data that are needed and the kinds of advances that can be made. The first basic task must be to survey every aspect of the field, to determine precisely what data are needed; which of these are available and which lacking, which are satisfactory and which are most deficient in quality, or precision of definition. Such a study would become a reference point from which to measure progress, and would reveal the problems to be attacked.

Without doubt, the first and most basic obligation of the Statistical Office is to assemble a complete file of the most recent and authoritative population figures for every primary political unit in the world. At first glance, the

work of compiling such a file seems a simple task, but in addition to the figures themselves, the sources must be given; it must be indicated whether they are *de jure* or *de facto* figures; the precise area covered must be known; it must be stated if the figures are enumerated or estimated and if certain classes of the population are excluded; the dates of the year to which the figures relate must be known and it must be determined if and in what manner the most recent figure differs from the previous figures.

Even a superficial survey of the needs for population data of the United Nations, the Specialized Agencies and other organizations which turn to the United Nations for data, shows that a file of simple population totals is merely a beginning. In the field of population, more than one international agency has expressed the need for distributions by sex and age, by marital condition, race, nationality, urban-rural and other characteristics. Data on the labor force are needed by sex and age, occupation, industry and class of worker. A surprising number of agencies require detailed statistics on international migration.

In the related field of vital statistics, birth and death data in considerable detail are basic to analysis of trends of population totals and composition. Touching the more social fields of health and welfare there is demand for infant mortality and cause of death figures, and for marriage and divorce statistics. A central file of information of this type would become a cornerstone of all demographic work of the United Nations and Specialized Agencies. The collection and maintenance of an extensive file of such data for all of the areas of the world is an endless task but is one that must be performed successfully if the United Nations is to serve satisfactorily the existing and future needs for international statistics.

But even a complete file would fail in

its function if methods for distributing the material were not concurrently established. The *Monthly Bulletin of Statistics of the United Nations* is one medium by which this material can be distributed. At the present time the *Bulletin* publishes total population trends for 58 countries or areas and current total birth, death, and infant mortality figures for approximately 35 areas. As other reliable and current data become available the demographic presentation in the *Bulletin* will be expanded and improved. It is recognized, however, that some other method for the distribution of current demographic data will have to be devised since up-to-date population figures are required for many more areas than can be shown in the *Bulletin*.

More important as a future medium of distribution for detailed data is the year book of demographic statistics which is now being planned by the United Nations. The preparation of plans for such a year book was requested by the Economic and Social Council at its fourth session on the basis of resolutions of both the Statistical and Population Commissions which recognized the need for extensive demographic data.

The plan for the contents and character of the year book are being made on the assumption that this publication is to be the central international source of demographic data. As such, the year book must serve the purpose of a general source book giving basic data in considerable detail together with accurate and adequate explanatory notes. At the same time, the volume must serve as a reference book containing readily interpretable rates, ratios and comparable data series.

In terms of contents, the year book ultimately will have major sections on population, households and families, labor force, international migration, natality, mortality, morbidity, and mar-

riage and divorce. The statistical data presented in the year book will be supplemented by certain technical information such as subject indexes, bibliography of major sources of national official statistics, technical explanations of methods, and footnotes giving details of areas covered, and other information essential for accurate definition of data given.

The development of the year book to the desired high technical level is a work which will require many years. Moreover, the year book must be developed in close accord with other national and international efforts for the improvement of statistical data. While tied to a certain extent to data which are available at present, the year book should also be a positive force encouraging the adoption of standard definitions, methods, and procedures. The year book tables could be progressively modified in order to indicate international agreements which may be reached on classifications, definitions, and related matters.

A second aspect of the program of the Statistical Office in the demographic field relates to the promotion of standard definitions, classifications, and computation methods. A professional audience will not need to be convinced that the first result of an attempt to compile an extensive file of international data will be the discovery that there is great variation in the type and quality of the data compiled by the separate nations. It remains the constant duty of both national and international statisticians to work for the elimination of these differences and for the persistent improvement of quality. The United Nations can play its part in this task by providing a medium through which the national statisticians can work toward agreement on acceptable and practicable standards and methods.

In the population field we still lack agreement on the meaning of "urban-

rural"; it remains practically impossible to compile internationally comparable population tables by occupation and industry; the classifications of race, nationality and related terms, adapted as they have been to the individualistic needs of each national census, present an unmanageable heterogeneity when viewed internationally.

In the field of birth statistics, the completeness of registration is not always adequately known or measured, and there are major differences between countries in the definitions and practices which distinguish between live and stillbirths. In this field too, greater uniformity in the detail of cross-classification of births by age of mother and birth order would help in an understanding of the true meaning of rapidly changing birth rates.

Mortality statistics represents one of the most highly developed statistical fields, yet here also there are grave deficiencies and problems. In parts of Asia, Africa, and America, particularly, the interpretation of death rates is hazardous because of inadequate levels of registration completeness. The problem of classification of the causes of death in order to obtain international comparability is by no means solved. International effort in this field over more than ninety years has resulted in general agreement on an international classification which is revised decennially to keep pace with medical thinking. But there still is little international uniformity in the theory and practices by which the cause to be tabulated is selected from the intricate syndrome of causes usually present at death and recorded on certificates of death.

Even if the methods of classification were theoretically perfected, the adequate tabulation of causes of death is dependent upon accurate medical certification of these causes, and this in turn is a function of the level of the whole economic and social life of the

country. True, these basic factors affecting medical statistics are not within the competence of a statistical office, but there does remain the problem of determining the significance of these differences as they affect international comparisons of mortality statistics.

The infant mortality rate is one of the statistical indices of wide interest and use. Varying enormously between countries, it is often regarded as one of the most sensitive indexes of social welfare. Yet it is perhaps subject to more important differences in compilation than any other measure. It is affected by under-registration in either the numerator or denominator, and by differences in the definition of a live birth, stillbirth, or infant death. And, for current figures especially, there is no uniform procedure for adjusting the infant mortality rate for rapid changes in the birth rate.

In the development of standards two important points should be emphasized. These problems and needs have long been recognized. National and international agencies have struggled with them for decades. The Statistical Office of the United Nations has no panacea to offer. Only that can be accomplished which arises from the requirements and potentialities of the statistical offices in the individual countries. An international agency can do no more than provide a machine by which these responsible agencies can effectively coöperate. A second point is that many of these problems of compilation and standardization are of particular interest to the Specialized Agencies and to the professional societies. In such cases the international agencies must work in co-operation if effective progress is to be made.

A third phase of the future program of the Statistical Office in demographic statistics is one in which a central international agency can be especially helpful to the national statistical offices. This is in the summarization and ex-

change of information on the organization, programs, and methods of national statistical offices. This function is illustrated by a recent resolution of the Population and Statistical Commissions regarding national censuses. This resolution requested the Secretariat, in effect, to keep informed on the census plans of member nations and provide for an exchange of information on these plans.

It is expected that similar surveys will be made of the sources by which other statistics of the demographic type are collected. Such studies, giving facts about the systems in use, the coverage, methods and definitions, will form a useful base for evaluating the comparability and validity of statistics. Publication of these surveys will give any country access to information on the statistical systems and methods of other countries.

These activities relating to the exchange of information, can potentially develop into one of the most useful functions of the Statistical Office and the other interested international agencies. The fund of information collected

can become a source valuable to any national agency wishing information on new census and registration procedures used in other countries, and can initiate a more direct exchange of scientific information between specialists in all parts of the world. An ultimate development could well be that sufficient staff would be available so that expert advice and assistance could be given to nations wishing specialized information on a great variety of operational or theoretical problems.

These various programs are still in the project and planning stages. A large number of international and regional agencies and offices are concerned with problems of population, public health, and vital statistics. There must be a joint effort so that the work of the various offices blend together and the work of each complements and supports the work of the others. If this can be achieved, the future of international vital statistics is bright, and this in turn will have a strong supporting effect on vital statistics work at the national, state, county, and city stages.

General Atmospheric Pollution

The Air Pollution Control Program in Cleveland *

HERBERT G. DYKTOR, F.A.P.H.A.

Commissioner, Division of Air Pollution Control, City of Cleveland, Ohio

FOR a considerable number of years the City of Cleveland has battled the problem of controlling air pollution. In this respect it was not in any way different from other concentrated industrial areas. As we all know, the industrial cities are still groping for a solution of this problem. The reasons for indifferent results are numerous, in fact, too numerous for discussion at this time. But it seems that the same old control programs continue to be hatched.

It may be of some value to let you know how many programs of this nature are brought about, and I am doing this in order to show the difficulties that attend a technical man when he is involved.

Generally speaking, a city attempts air pollution control when pressure is exerted by the community, vocal through its organizations and newspapers. The claim is made that there is damage to health and property, that the city is dirty and is gradually going to seed. These rumblings and public statements finally reach the ear of the council or board of aldermen who, as a first step, appoint a committee to deal with this question. When this is done, public hearings are held at which every interested party is heard. These public hearings go on for several months, and

when the committee has become thoroughly confused, private deliberations may be held in order to sift out some conclusions and develop a plan of action. Since politics is politics in any land, the technical counsellors are ignored, an ordinance is drafted which throws the whole "book" at the people, and the authority for the enforcement of this ordinance is placed in the department which is most readily at hand at that time. Thereafter, the community stimulus for action abates, the ordinance may be found to be too cumbersome to be enforceable, and peace settles down again on the community.

There are many variations on the above theme, and there are more angles than either the mind or eye can perceive; but, in the main, that is the usual situation. Such confusion of ideas as to how to deal with the problem of air pollution control is evidenced to a significant degree by the results of a survey made by the U. S. Bureau of Mines and published in *Information Circular No. 7090*, October, 1939, according to which the authority for this activity was distributed approximately as follows:

- 24 per cent in Public Works Departments
- 23 per cent in Building Departments
- 20 per cent in Public Safety Departments
- 18 per cent in Health Departments
- 6 per cent in Fire Departments
- 9 per cent in various other departments

We, in the City of Cleveland, were well aware of this state of affairs, and we soon decided that, if we could not

* Presented at a Joint Session of the Industrial Hygiene and Engineering Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

improve upon it, we at least would be different.

Until this very year, the authority for the control of air pollution in Cleveland was placed in two departments. As a result of this divided authority, officials were uncertain where their zone of activity began or ended; and both industry and residents had to deal with two sets of officials, which state of affairs created quite a little dissatisfaction. Needless to say, results in the way of control were inadequate, and the entire community felt that major changes in administrative organization had to take place in order to remedy this undesirable situation.

As a first step to correct this situation, the mayor appointed a representative civic committee to channel the best thought of the community; and we were consulted in their discussions. Several plans were submitted, but close inspection revealed that they were impractical. Finally, a plan was adopted whereby the three phases of air pollution control, smoke abatement, industrial nuisances, and industrial hygiene, were to be combined into a new independent division. This decision was based upon the reasoning that there are two main sources of air pollution: (a) from industrial processes, and (b) from the combustion of fuel, and that these sources of air pollution could best be controlled by an approach from three avenues:

1. By controlling pollution at its point of origin in the plants through a bureau of industrial hygiene.
2. By controlling excess emission of pollution into the neighborhood through a bureau of industrial nuisances.
3. By controlling smoke from an industrial, residential, or commercial source through a bureau of smoke-abatement.

An ordinance setting up a new Division of Air Pollution Control was introduced in Council last fall. Many public hearings were held at which our line of reasoning was upheld. This new

division was located in the Department of Public Health and Welfare because it was felt that it belonged there as its functions came within the wider concept of health which does not limit itself to the absence of a physical disability but comprises as well a state of mental and social well-being. This ordinance was finally enacted on May 29, 1947.

It may be well at this time to say a few words as to how these three bureaus operate and how they are intended to operate.

In so far as the Bureau of Industrial Hygiene is concerned, there is little that I can say to you since ours does not operate differently from that of any other like official agency. However, we go one step further than most such bureaus as we bear in mind, when making recommendations for environmental improvement in plants, that the discharge of the various contaminants be made in such a manner as to preclude the possibility of creating a nuisance in the neighborhood.

In regard to the Bureau of Industrial Nuisances, this is really the catch basin for all complaints arising from industrial operations; and contrary to the Bureau of Industrial Hygiene which has only to deal with industries, this particular bureau deals both with the public and the industries. Complaints come in to the office, and the complainants are visited in order to investigate the real nature of the complaint. The plant against which the complaint is made is then visited, and the justification for the complaint is assessed. If the complaint is justified, steps are taken to remedy the situation. These steps are not arbitrary as the violating plant is consulted and a mutually satisfactory solution worked out, which sometimes may lead to the recovery of valuable wasted material. Care is also taken by the Bureau of Industrial Nuisances not to make recommendations which will interfere with any previously made by

the Bureau of Industrial Hygiene; therefore, a very close coöperation between these two bureaus is absolutely necessary. Human angles are also projected into this particular activity since it deals with the general public, such as personal feuds, attempts to make capital out of the complaint by way of compensation either direct or indirect through the sale of an adjacent house, or merely a morbid attitude toward life. You will gather from this brief explanation that this Bureau of Industrial Nuisances has a tidy job on its hands.

In regard to the Bureau of Smoke Abatement, its activity is based upon a code which provides certain regulations in regard to the operation of fuel-consuming devices. Although the code has been in existence only a few years, some parts of it are already outdated, and our next concern will be to bring it up to date, and simplify it. This bureau also has close connection with the Bureau of Industrial Nuisances because of the fact that some cases where excessive smoke is produced, arise from both combustion and metallurgical processes, and close coöperation is also necessary in this particular instance.

Now, I must point out that mere passage of this ordinance does not end the story; it is only the beginning. Carrying into effect an ordinance of this type must be predicated on common sense and a realistic attitude, and it is our firm belief that the following considerations are absolutely essential to the success of any air pollution control program.

1. The community must not be misled into believing that elimination of air pollution is attainable—it definitely is not. All that can be done is to reduce its concentration to a tolerable level and to maintain it at that level.

2. There must be no thought of arbitrarily closing down violating plants; on the contrary, their coöperation must be enlisted to

make them good neighbors and preserve good public relations. All industrial centers try to induce the influx of additional plants for the benefit of the community and not to drive them away.

3. There is no magic in air pollution control but only hard work. Therefore, to be successful, the program must be long-range, and any statement to the contrary is fallacious.

4. The program is costly, and unless the city administration is prepared to undertake it on a real long-range basis, the attempt had better not be made at all. Part of the cost may be returned in fees for permits and inspections.

5. The support and coöperation of the entire community, especially the newspapers, must be obtained. This is self-evident as no law can be enforced unless it meets with the approval of the people upon whom it is imposed.

6. The enforcing agency must be staffed with career men sincerely imbued with the necessary civic spirit. A good law can be seriously impaired by poor administration.

7. The personal and material benefits that can be derived from a properly administered air pollution control program based upon common sense and fairness are many.

These are our beliefs in Cleveland. We feel that we have the right groundwork for success. The program has already proved itself because, during the short period that we have been in action, very large sums of money have been expended by industries to control and reduce their contributions to the air pollution of the city. This was done without "cracking" the so-called whip, and was based entirely on free coöperation and good selling of the idea that we all have to be good neighbors.

We know that our division faces a complex problem, involving technical, economic, and human factors. Much will depend upon our research work in developing reasonable standards of general air pollution, our awareness of costs, and our understanding of human psychology; but we are hopeful of eventual success.

General Atmospheric Pollution

Some Work in Pittsburgh Air Pollution Problems *

SUMNER B. ELY

Superintendent, Pittsburgh Bureau of Smoke Prevention, Pittsburgh, Pa.

THE Industrial Hygiene Section has asked me to say something of the work being done in Pittsburgh.

This question will divide itself into two parts, viz: the smoke problem and the dust problem. Of course both are included under General Atmospheric Pollution. The smoke problem, however, is a combustion problem and can be corrected, but the matter of dust and dirt is quite another problem depending on many factors.

Consider the smoke problem first. Pittsburgh has done a great deal toward smoke elimination but unfortunately there is no way of knowing what proportion of smoke is in an atmosphere which also contains fog, dust, haze, and other contaminants. While we can measure the pollution as a whole, we cannot tell the proportion of smoke. We are therefore obliged to rely on general observation. We have cleared some 1,500 smoking stacks in Pittsburgh during the last 4 years and this must have an effect on general conditions. We believe that visibility has improved, fogs are cleaner, etc., but, because of variable weather conditions, a definite quantitative figure is not available.

Now, coming to the dust and dirt problems—as I said, its solution depends on many factors. The weather is probably the most important factor.

Let me illustrate: Some six or eight years ago Pittsburgh undertook a very elaborate dust fall collection. We had 100 receptacles on roofs scattered throughout the city and for some two years the contents were collected from these cans every month. The insolubles were analyzed for volatile matter, fixed carbon, and ash. The ash was further analyzed for iron and silica. The solubles were analyzed for sulfur.

In addition to the dust collecting cans we had an Owens Automatic air filter, an Owens jet dust counter, and an impinger dust counter. We have a very large and impressive volume of data. In all this mass of data, unfortunately, weather conditions were not recorded. Where we have been able to trace back through U. S. Weather Bureau and other records, we find that a relation seems to exist between the amount of dust fall and weather conditions, especially that of temperature inversion.

I assume everyone here understands the term "inversion" but perhaps I should briefly explain it. When the earth is warmer than the air, there is a natural rise of the whole atmosphere, warm air being lighter than cold air, which carries the pollution up with it, and we have a bright clear day. But, when inversion takes place: i.e., when the earth is colder than the atmosphere, it cannot rise and forms what is called a meteorological lid, which holds the pollution down.

* Presented at a Joint Session of the Industrial Hygiene and Engineering Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

Our records indicate that with all industries down (Sundays, holidays, etc.), if a heavy lid existed, we would get a large dust deposit all over the city, but where there was no lid, yet with all the mills running full and throwing out a great deal of pollution, we found a small deposit. In other words, what the cans were really measuring was a weather condition.

We have run a short test indicating this condition. During February, 1946, there was a general strike and the mills of the district were completely shut down for a short period.

We had on the roof of the City-County Building what might be called "an electric air pollution recorder," an instrument designed at Mellon Institute for Industrial Research. A very few were built and we were fortunate enough to obtain one. The instrument contains a paper tape about $\frac{1}{2}$ " wide which is drawn over a magnet. About $1\frac{1}{2}$ " above the tape, directly over the magnet, is an electrode of high voltage. Atmospheric air is drawn in through a tube surrounding the electrode and, coming down against the paper, deposits any dust on it. The paper moves over the magnet very slowly—1" per hour, so that 24" of paper show the dust deposited for each hour for a day and a night. The shade on the paper indicates the amount of dust in the atmosphere.

We ran this instrument continuously during the steel strike with the mills shut down and again after the strike was over and the mills operating. We have mills all around us at varying distances. The nearest are some $1\frac{1}{2}$ miles east and others to the west about the same distance. When the mills started after the strike, it took them some two weeks before they were running at full capacity again.

Therefore, we have record tape showing three conditions, mills entirely closed down, mills running at about 60 per cent capacity, and mills running full. We cut the continuous paper tape into 24 hour lengths to show each day above the other.

In order to compare results, we chose an arbitrary scale of shades. We assumed that the darkest shade carried 4 dust units and then graded the shades down to white with zero units. We could only measure the shades by estimating them by eye.

The results of this estimate show the average dust per hour to be as follows: Mills off show 1.77 units of dust per hour; mills 60 per cent on, 1.61 units of dust per hour; mills full, 1.68 units of dust per hour. These figures mean that the three pictures show practically the same amount of dust deposited in each case. In other words, so far as general atmospheric dust conditions at our building were concerned, it did not make any difference whether the mills were running or not.

Furthermore it is very noticeable from the pictures that dust is deposited in mornings and nights, while in the middle of the day the tape is comparatively white. That is: inversion was taking place nights and mornings, but when the sun came out in the middle of the day and warmed up the earth, the lid tended to disappear and the tape record to show white.

This is really what should be expected since the tests are reflecting weather conditions. There were no storms, violent winds, or other extraordinary disturbances during the period of the tests. One thing the test does distinctly show is that the measurement of dust conditions does not reflect combustion conditions.

General Atmospheric Pollution

Los Angeles "Smog" *

CHARLES L. SENN

*Engineer-Director, Bureau of Sanitation, City Health Department,
Los Angeles, Calif.*

ON winter mornings when most air pollution control officials are especially busy controlling smoke, soot, and fly ash from overloaded heating plants, Los Angeles residents can usually see distant snow-capped "Old Baldy" mountain with sparkling clarity. On the other hand, air pollution conditions on many summer and fall mornings have caused "smog" stories to become favorites of Hollywood radio comedians. The need for cleaning the air has become a major public issue. Office and industrial workers frequently find a disappointing contrast between high, clear and sunny mornings in residential areas and the hazy, irritating, burned-petroleum-scented blanket accumulated in the business and industrial section of the Los Angeles River basin.

Although this peculiar condition had existed for a number of years and was reported by the press in 1940, it did not become acute until July, 1943, when the haze and irritants were noticeable between 8:00 a.m. and 12:00 noon on several days. On July 26 they became so acute that most people in the affected area were using handkerchiefs to wipe tears from red, smarting eyes. Every telephone in the Health Department was busy answering complainants. On that morning smoke from a heavy freight train produced a black cloud that hung

near the ground, was several hundred feet wide, and extended for several miles. Smoke from chimneys spread out and formed a black cloud that extended for more than a mile from their source. According to the weather bureau the wind velocity was less than 2 miles per hour. A further examination of the records of the weather bureau, for days when air contaminant accumulations were heavy, failed to show any direct correlation between smog accumulations and humidity or recorded wind directions.

We assigned sanitarians to strategic vantage points while others drove across and observed the affected metropolitan area. These observations and information received from complainants showed that the hazy accumulation seemed to descend on the entire area, approximately 10 miles in diameter, within a period of not more than 15 minutes. On each of the mornings the air was perfectly clear until about 8 o'clock and was hazy by 8:15. On one morning, from the City Hall tower, we could clearly see the mountains 20 or more miles away but could barely see cars on the street below. We looked down on a level lake of dark grey haze.

Meteorologists pointed out that the upper surface of this haze was actually the base of a marked "temperature inversion." On clear, calm nights the ground heat is lost by radiation and cold air drains from surrounding mountains to the river basin. Direct and reflected rays of the morning sun warm

* Presented at a Joint Session of the Industrial Hygiene and Engineering Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

the upper air causing the temperature at an elevation of 1,000 feet to be as much as 30° warmer than near the ground. This temperature inversion acted almost the same as a roof over the city, preventing contaminants from escaping to the upper air. This condition, coupled with the very low horizontal air movement and lack of turbulence, caused all contaminants to be accumulated in the vicinity where generated.

With conditions so unfavorable to the dispersion of smoke we believe our control measures must eliminate even those sources of air pollution not significant in most communities. We have no coal-burning furnaces or boilers, and nuisance conditions occur only on warm days when heating plants are not operated. During such periods many industrial boilers are operated on gas available at "off peak demand" rates.

We made a number of airplane and blimp observation trips over the entire metropolitan area. Certain specific sources of visible smoke and contaminants were readily apparent. These included refineries located near the ocean shore approximately 20 miles from the affected metropolitan area. Smelters, chemical plants, packing plants, and oil-burning boilers in a large industrial area located east of and within 2 miles of the metropolitan area were heavy contributors to the visible smoke. Oil-burning steam railroad engines, particularly switch engines, caused a huge amount of dense, black smoke. The burning of combustible refuse of all kinds in backyard incinerators, at commercial and industrial establishments and at public dumps was producing heavy accumulations of grey and black smoke. Major highways and traffic arteries, particularly those heavily traveled by smoking Diesel trucks, produced long bands of smoky haze accumulations.

Control of visible smoke was our first goal. Simultaneously we began studies to determine the chemical na-

ture and sources of the irritants. At the request of the Health Officer, Mayor Fletcher Bowron made personal appeals for assistance to the U.S. Public Health Service and other federal agencies. He tried to encourage a local university to undertake a combination meteorological and chemical study, and the Los Angeles County Board of Supervisors agreed to pay the entire cost of the investigations and research. None of these agencies agreed to undertake the project.

Both the city and county health departments established Bureaus of Air Pollution Control and these worked together in developing identical ordinances and uniform programs. The Board of Supervisors agreed to provide free control services to the 40 or more incorporated cities in the county but few accepted the offer. Unless an incorporated community adopted the regulations, neither Los Angeles City nor the county had any legal right to effect control in that area.

Even with large, uncontrolled industrial communities continuing their discharge of air pollutants, a marked improvement has been accomplished. Joint City-County Smoke Abatement Hearing Boards, working with railroad officials and representatives of the Brotherhoods, have nearly eliminated railroad smoke. This is being accomplished by hearing cases presented by railroad smoke specialists of the departments, after which the railroad officials find and eliminate the cause. When it was decided it was impossible to eliminate smoke from steam switch engines, the railroads substituted Diesel power.

Truck owners and the drivers' union are represented on the Diesel (truck) Smoke Control Hearing Board. The city Diesel truck specialist has encouraged installation of a number of dynamometers for adjusting fuel injectors for maximum efficiency and smokeless operation under various load conditions. H. E. Kunkel, the Air Pollution

Control Director, conducts regular classes in smoke observation for city traffic officers. These officers cite violators to the Hearing Board. Mechanical adjustments of the offending engine, or improved operation by the drivers, have almost eliminated the former common clouds of black truck smoke. Articles and pictures by our Diesel specialist have appeared in the truck drivers' and owners' magazine. A major oil company has made an excellent colored moving picture on smokeless operation of Diesel trucks.

Industry has been exceedingly cooperative. The Chamber of Commerce has for several years held bi-weekly meetings of its Committee on Air Purification. Technical consultants from the petroleum industry have been most helpful in correcting smoke from oil burning boilers. Refineries have spent hundreds of thousands of dollars in abatement equipment. Lumber, paint and varnish manufacturers, smelters and other industries are doing extensive research. While a number of court cases were necessary, most accomplishments have been on a cooperative basis.

Funds have been made available for construction of a number of public incinerators. Plans are being formulated for public collection of combustible refuse to eliminate the several hundred thousand smoke-producing back-yard incinerators.

Preliminary information indicates that a major reduction in visible smoke has already been accomplished. During the year 1943, electrostatic precipitator samples gathered on days when irritants were particularly noticeable showed a concentration of particulate matter ranging from 15 to 42 mg. per 10 cu. m. During the year 1947 similar samples showed a maximum concentration of 7 mg. per 10 cu. m., or a reduction of from 100 to 600 per cent. Visual observations also indicate a remarkable reduction in the amount of man-made haze,

although much remains to be accomplished in this regard.

Naturally one of our first objectives was to locate and identify the eye-irritating chemicals. Industrial type hygiene sampling investigations made by the city and county failed to reveal any one common lachrymator in quantities sufficient to be considered responsible for the eye irritation. The County Health Department also arranged for analyses of mass spectograph samples collected in various ways including freezing with liquid nitrogen, but so far no conclusive results can be reported. The two chemicals present in the air in significant amounts are sulfur dioxide and aldehydes. Both serve as rather accurate indices of the eye irritant condition since whenever eye irritation is noted the concentration of these chemicals is high. Sulfur dioxide, however, has never been found in amounts greater than 0.6 p.p.m. This is several hundred per cent lower than is regularly found in certain eastern and midwestern coal burning communities where eye irritation is not a problem. The maximum aldehyde concentration was also 0.6 p.p.m., an amount insufficient to account for the irritation.

There is some indication that exhaust from internal combustion engines is a major contributor. Tests made in an improperly ventilated tunnel during heavy traffic indicate heavy concentrations of aldehydes and marked eye irritation at times when the outside air is clear. Tests of car, truck, and bus exhausts show that the discharge of aldehydes is high when the engine is decelerating. The general odor present during days of eye irritation is similar to the discharge from automotive buses and the irritating effects of both are similar. Because of this it is difficult to predict with any assurance that the control of industrial and railroad smoke will eliminate the eye irritation. Further studies need to be made on the effect of automotive ex-

haust and possibly some control measures will be necessary.

The county arranged for certain limited studies by two local universities. Results of the chemical and physiological studies have not been officially announced, but they are not conclusive. Meteorological studies substantiate our earlier observations on the effects of weather conditions on air pollution.

Recently we made the first of a series of airplane observation flights which we hope will shed further light on the major sources of visible haze. This is a volunteer project of the National Guard Air Unit, which is justified because reduced visibility, caused by man-made haze, is a definite flight hazard.

Under stimulation and public support developed by an active program of the *Los Angeles Times*, the last session of the California Legislature adopted a law permitting formation of County Air Pollution Control Districts with authority for enforcing regulations in all sections of a county. There is now being formed a Los Angeles County Air Pollution Control District. Unfortunately, because the former County Health Officer was anxious to be relieved of the responsibility for air pollution control, the new law provides that the districts shall be separate from the Health Department. While the City of Los Angeles is a part of this smoke district, the Mayor and Council have appropriated funds for continuing the city's Bureau of Air Pollution Control within the Health Department. We have felt that air pollution control is definitely a part of our sanitation program; that we cannot properly refer complaints about odors, smoke, and other nuisances to another agency; that our district sanitarians can take care of many of the

minor complaints about air pollution, referring to the specialist only those more involved problems that require technical guidance. We shall look to the County Bureau for the major research and will cooperate with them in that as well as in the entire enforcement program.

SUMMARY

Los Angeles experiences, on certain summer and fall mornings, heavy accumulations of types of air contaminants causing serious smarting of the eyes. This accumulation is due to a low and marked temperature inversion accompanied by extremely light winds or total absence of horizontal air movement. The actual sources of the irritants have not been discovered, but a program has been inaugurated for eliminating all sources of visible air pollution. Due to the large number of complex chemicals that could be produced by incomplete combustion of petroleum products we have not been able to identify the irritant. There is some possibility that the chemicals in the air are different from those leaving the sources. The effect of hydrolysis, oxidation, catalytic action of sunlight, and other factors must be considered. To isolate and identify the chemical is a complex problem. Meteorological investigations and regular airplane observations will be continued in the hope of gaining more definite knowledge of the location of the major pollutant sources.

Our experience indicates that health department, engineering, and industrial hygiene bureaus, working together, form a logical team for air pollution control; and that air pollution control should be accepted as a health department responsibility.

General Atmospheric Pollution

New York City's Atmospheric Pollution Control Problems *

ARTHUR C. STERN

*Chief, Engineering Unit, Division of Industrial Hygiene and Safety Standards,
New York State Department of Labor, New York, N. Y.*

THE day-to-day activities of the New York State Labor Department in securing the installation of dust control devices on industrial plant discharges to the atmosphere and in preventing the installation of gaseous discharges from those plants which might prove nuisances to neighboring premises, has been the only form of air pollution control carried on as the continuous full-time activity of a public agency in New York City during the ten years from the completion of the City Health Department's Air Pollution Survey in 1937 to the rebirth of activity by that department during the past year. During this time a number of requests from New York City authorities for action in the case of individual plant complaints and problems have been received and acted upon. However, the only official contact with large-scale air pollution control in the city occurred in 1943 when, at the request of the City Health Department, a special study was made of means for decreasing the rate of soot fall in the Williamsburg area of Brooklyn.

In general, however, the State Labor Department has no jurisdiction in the field of General Atmospheric Pollution and has rendered assistance to municipalities only upon request from the municipality and only on a consulting

basis. It was on this basis that the department aided the City of Niagara Falls in the writing of its recently adopted air pollution charter amendment, ordinance, rules and regulations; aided the City of Buffalo in a problem involving dust dissemination from a cement plant; and is currently aiding the Township of North Castle in the solution of its smoke and cinder problem. Because these matters are beyond the jurisdiction of the Labor Department, it must be fully understood that the opinions expressed in this paper are solely the author's and not necessarily those of the department.

New York does not have a bad reputation as a smoky, smoggy, or foggy city. It is traditionally a hard coal rather than a soft coal city, and its air pollution problem is not dominated by any single industry or group of industries making abnormally large contributions to the dust or smoke load of the city's air. If there is any outstanding single group of offenders it is the public utility steampower plants, both privately and publicly owned. The one thing above all others that the city has to fear is a sudden forced change-over from hard to soft coal which would throw potentially smoky fuel into the several hundred thousand furnaces designed for, and now burning, hard coal. A severe fuel oil famine might have the same effect, since large segments of former hard coal burning load has been converted to the use of fuel oil.

The emission of atmospheric pollu-

* Presented at a Joint Session of the Industrial Hygiene and Engineering Sections of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 9, 1947.

tion has been regulated since 1903 by two sections of the New York City *Sanitary Code*. These provisions stipulate that

1. No person shall allow smoke, cinders, dust, gas, steam, or offensive odor to escape or be discharged from any building to the detriment or annoyance of any person not therein engaged.

2. The emission of dense smoke is specifically prohibited without requiring proof of detriment or annoyance, and all persons participating in permitting or causing that emission as owners, tenants, managers, engineers, firemen, etc., are severally liable therefor.

3. All buildings, locomotives, and vessels are subject to the above prohibitions.

In 1937 New York City adopted a new *Building Code*, applicable to all structures built after that date, which includes the following provisions:

1. A requirement that plans and specifications for fuel burning equipment installations must be filed with and approved by the Commissioner of Housing and Buildings prior to installation.

2. A stipulation that the New York City Board of Standards and Appeals shall promulgate rules for the design and installation of fuel burning equipment and that installation shall comply with these rules.

3. A statement that fuel burning equipment shall be so designed that "under normal conditions of operation they will not discharge smoke, soot, cinders, or fly ash or other residue in such quantities as to cause annoyance to the public or injury to business or property."

4. A limitation of emission to 400 grains per 1,000 cu. ft. of combustion gases in the case of solid fuels and a prohibition of visible discharge of soot or smoke in the case of liquid fuel; cinder or fly ash catchers are otherwise to be required.

5. Instructions as to the conduct of the test for maximum cinder or fly ash emission.

In order to activate this program, these five provisions require the Board of Standards and Appeals to promulgate rules; and the Department of Housing and Buildings to examine fuel burning equipment plans from an air pollution control viewpoint, and to test com-

pleted installations from this same viewpoint. None of these things has been done in the ten years since the adoption of the *Building Code*, with the result that these *Building Code* provisions still remain merely statements of intent on paper. Only those *Building Code* rules on heating appliances, combustion, and chimneys which relate to the structural safety of buildings and fire prevention therein are at present enforced, there being no apparent attempt to enforce those parts of the rules relating to the emission of smoke, cinders, and fly ash.

In contrast to this, there has been a continuous record of enforcement of *Sanitary Code* provisions regulating atmospheric pollution. Over the years this enforcement has alternated between periods of time when all rank-and-file sanitary inspectors enforced these regulations along with their multitudinous other inspectional duties and periods of time when certain inspectors were designated as smoke inspectors or members of a smoke squad and thereby relieved of all duties other than enforcement of atmospheric pollution regulations and the conduct of educational work along these lines. During the ten years from 1936 to 1946, the rank-and-file inspectional approach was employed. For a large part of this time very little, if any, enforcement beyond that resulting from specific citizens' complaints was attempted. However, during the past year a modified form of the smoke squad approach has been once again adopted by the special assignment of a group of sanitary inspectors to form a smoke squad.

At present the smoke squad consists of 11 inspectors and one supervising inspector attached to the Bureau of Sanitary Engineering and responsible to the director of that bureau, a sanitary engineer. This group functions in so far as possible in a staff capacity presently working on 6 problem area demonstration projects and two special projects,

and on educational and training activities. Routine complaints are presently being funnelled by the squad to the 50 to 60 regular sanitary inspectional field men in each borough through one man in each borough specially designated and trained for this purpose by the squad. However, it is anticipated that eventually all inspectors will receive this special training. The Health Department has estimated that the Smoke Unit is responsible for causing the initiation of over \$2,000,000 worth of plant modernization and improvement during the past year; and \$3,500,000 worth in the year to come.

It should be noted that the air pollution control activity outlined above is being accomplished by the assignment of inspectors who previously had general sanitary inspectional duties and not by the appointment of new inspectors. Since air pollution inspectional activity had previously been a very minor part of the sanitary inspector's job, the diversion of 10 per cent of the staff to full-time work in this field and the increase in the percentage of time spent on this work by the rest of the field staff cannot but result in a decrease of time available for their other important inspectional activities. In 1928 the Health Commissioner's Air Pollution Control Committee advised that a staff of 88 inspectors plus an administrative staff of 16 would be necessary to carry on a full-scale air pollution control program in New York City. In 1933 a very competent administrator of the air pollution control program of a mid-western city estimated New York City's need as 62 inspectors plus an administrative staff of 20. Granting that these estimates are as much as 100 per cent too high, they nevertheless indicate the need for an air pollution control staff comparable in size to the present sanitary inspectional staff or conversely the use of 100 per cent of the time of the present staff to accomplish the kind of

air pollution control job envisioned by the Commissioner's advisory committee in 1928. The latter being obviously impossible, the former indicates the need for a vastly enlarged staff, if this work is to be brought to a successful conclusion.

At such time as the Board of Standards and Appeals prepares rules for the design and installation of fuel burning equipment, the Department of Housing and Building will also need additional personnel to do the job. Neither this additional staff nor the additional staff which the Health Department would require can come into being without a fight for the necessary appropriations. The best strategy in the fight to obtain these appropriations would therefore seem to be, first to eliminate duplication of personnel and appropriations by combining the Health Department and Housing and Building Department units into one unified group. It is fundamentally unsound to have one city department responsible for approving and testing new construction and another one responsible for it thereafter. Approval and testing of new constructions is an engineering job; smoke inspection is not. In a unified set-up, engineering guidance to the entire program is available at no extra cost; whereas in a non-unified set-up full-time engineering guidance of the inspectional program either has to be obtained at extra cost or dispensed with entirely. A unified air pollution control unit of the type needed could function equally well in the Health Department, the Housing and Building Department, or under a commission, commissioner or board independent of both departments.

Early this year the Health Commissioner appointed 12 committees to advise him on air pollution control matters. They are respectively Committees on Public Cooperation, Harbor Craft, Railroads, Public Utilities, Automotive Transportation, Laws and Legislation,

Fuel Oils, Solid Fuels, Real Estate and Industry, Public Health Aspects, Plant Operation, and City Departments. A Subcommittee on Civic Group Coöperation was formed from the Committee on Public Coöperation. The Committees on Plant Operation, Fuel Oils, and Solid Fuels have combined efforts to become a Technical Advisory Committee on Fuels and Plant Operation. The department states that all but two of these groups have been active, three of them having already submitted written reports to the Commissioner. The Committee on Civic Group Coöperation has prepared a two page pamphlet for distribution to civic groups eliciting their coöperation, and is planning a pamphlet on combustion in the near future. Active participation in the city's smoke control program by the Committee on Railroads has already begun, with the roads themselves disciplining firemen for violation of the smoke ordinance due to non-coöperation or carelessness.

In conclusion, it should be noted that the city's program has the active support of powerful elements of the press

but that the public as a whole is apathetic to the problem. A citizens' committee has been formed, the author being one of the organizers, to attempt to break down some of this apathy and to support the official program of the city. A firm foundation of factual data upon which to base a control program is available to the city in the *Report of the Air Pollution Survey* which gathered data from 1935 through 1937. Most of these data have been published,¹ but the unpublished portions as well are available to the city authorities to guide them in planning their efforts. In 1943, soot fall studies of limited scope were reinaugurated by the Health Department, and have been continued to date. However, considerably more current data on the level of pollution in the city's air should be continuously made available to support a control program of the magnitude that the world's largest city deserves.

Medical Attendance During Terminal Illness*

MARTA FRAENKEL, M.D., F.A.P.H.A.

*Research Associate, Department of Preventive Medicine and Community Health,
Long Island College of Medicine, Brooklyn, N. Y.†*

HOW adequate is the amount of medical care which people living in various parts of the country receive? The collection of reliable information on this score has been attempted in various ways. At least on one occasion, the data from death certificates were used for this purpose: in his testimony in the Hearings on the Economic Security Act in 1935, Dr. F. J. Underwood, Health Officer of Mississippi, quoted figures of the number of persons who, according to the information on death certificates, died "without any medical care whatsoever."

The study, which is briefly summarized in this paper, was made in the Division of Health and Disability Studies of the Bureau of Research and Statistics, Social Security Administration. Data on death certificates were analyzed for information on medical attendance during terminal illness. These data indicate possible answers to such questions as: What proportion of deaths occur without any medical attendance or with what appears to be inadequate medical attendance during terminal illness? What proportion of such deaths occur at home and what proportion in hospitals? How do these proportions

vary among states? What proportion of home deaths occurs in communities of different size and how does the medical attendance of home deaths vary with different size communities? What are the age and race characteristics of persons who die unattended at home?

DESCRIPTION OF THE SAMPLE

This paper presents some of the results of an analysis of a sample of death certificate transcripts. A total of 18,484 certificates from seven states, for the year 1941—the latest year in which substantially pre-war conditions prevailed—constituted the sample. The seven states were chosen, subjectively not mathematically, to represent different geographic areas of the country and other socio-economic factors believed to be important in evaluating medical attendance during terminal illness. The seven states of the sample were: Arkansas, Colorado, Indiana, Missouri, New Jersey, North Dakota, and Virginia. The deaths which occurred in these states constituted 13.8 per cent of all deaths in the United States in 1941.

From the total number of death certificates for these seven states, the National Office of Vital Statistics—at that time, the Division of Vital Statistics of the Bureau of the Census—selected the state samples. The total of 18,484 death certificates in the sample constituted nearly 10 per cent of all the deaths occurring in the seven

* Presented before the Vital Statistics Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

† Summary of a study conducted by the author while a member of the staff of the Division of Health and Disability Studies, Bureau of Research and Statistics, Social Security Administration, Washington, D. C.

states. The samples for the individual states, however, varied from slightly less than 5 per cent for New Jersey to slightly more than 20 per cent for Colorado.

For the purpose of this study, deaths due to accidents and violence—rubrics 163 through 198 of the *International List of Causes of Death*—were excluded if death occurred within 24 hours of the accident, since in many instances medical attendance would have been impossible. There were 1,201 such deaths. Eighteen other certificates had to be excluded because the data on medical certification were not complete.

For that part of the study relating to place of death, an additional 607 certificates were excluded because the deaths occurred in places other than home or hospital. For the more detailed analysis of home deaths, deaths of infants who died within the first 8 days of life were also excluded.

DEFINITIONS ADOPTED FOR THIS STUDY

Medical attendance during terminal illness was classified into four categories depending on the entries in the "medical certification" section of the death certificates—items 20 through 23 of the standard certificate.* The four categories of medical attendance used in this study are:

1. Without *any* attendance—if the deceased was not attended by a physician during terminal illness and if no physician was present at time of death. If death occurred in a hospital, it occurred before medical attendance could be given.

2. Without *recent* attendance—if the certifying physician attended deceased in the past but had not seen him alive on the day of death or on the preceding day.

3. Pre-death attendance only—if the cer-

tifying physician attended the deceased only on the day of death or on the preceding day.

4. Routine attendance—if the certifying physician attended the deceased on the day of death (or the preceding day) and for at least 2 days before death.

LIMITATIONS OF THE DATA

This classification does not have uniform meaning for deaths of different types; for instance, if death occurs suddenly and unexpectedly, as in many cases of cerebral hemorrhage and coronary thrombosis, no protracted medical attendance during terminal illness can be expected. Unfortunately, in many instances the causes of death as recorded on the death certificates do not indicate clearly whether or not death did occur suddenly; vague diagnostic terms (frequent among them "cardiac failure") and lack of information on duration of the condition recorded as the cause of death often dim the picture, especially when the death occurred without any attendance or with pre-death attendance only. This is an important limitation of the study.

Another limitation is that the death certificate shows only the attendance of the particular physician who signed the certificate. The figures presented here are, therefore, subject to a limitation arising from lack of information for patients who changed their physician during their terminal illnesses or who, shortly before death, transferred from home to hospital or from hospital to home.

TYPE OF ATTENDANCE

For this part of the analysis, the effective sample consisted of 16,658 death certificates. Table 1 shows, for each state, the percentage distribution of these deaths by type of attendance and the average, weighted by the total number of deaths occurring in each state, reduced for "immediate external" deaths and deaths in miscellaneous places by the same proportion as were

* These are the items which give date and time of death; the dates from and to which the certifying physician attended the deceased; the date on which the certifying physician last saw the deceased alive; the causes of death; additional information on deaths from external causes; and whether or not the person certifying to the death was a physician.

TABLE 1

*Analysis of 16,658 Death Certificates from Seven Selected States, 1941¹**Percentage Distribution of Deaths by Type of Medical Attendance*

| Type of Medical Attendance ² | Arkansas | Colorado | Indiana | Missouri | New Jersey | North Dakota | Virginia | Weighted Average |
|---|----------|----------|---------|------------------|------------------|--------------|----------|------------------|
| All types | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Without any attendance | 19.2 | 9.2 | 7.8 | 8.7 | 6.5 | 7.8 | 12.1 | 9.5 |
| Hospital | 1.2 | 0.8 | 0.7 | 2.4 ⁴ | " | 0.4 | 0.7 | 1.0 |
| Home | 18.0 | 8.4 | 7.1 | 6.3 | 6.5 | 7.4 | 11.4 | 8.5 |
| Without recent attendance | 14.1 | 8.0 | 11.0 | 14.3 | 3.6 | 9.4 | 13.8 | 10.6 |
| Pre-death attendance only | 14.9 | 15.6 | 13.0 | 11.9 | 12.1 | 18.8 | 17.3 | 13.7 |
| Hospital | 2.9 | 7.5 | 5.0 | 3.9 | 8.6 ⁵ | 8.8 | 5.4 | 5.7 |
| Home | 12.0 | 8.1 | 8.0 | 8.0 | 3.5 | 10.0 | 11.9 | 8.0 |
| Routine attendance | 51.8 | 67.2 | 68.2 | 65.1 | 77.8 | 64.0 | 56.8 | 66.2 |
| Hospital | 18.5 | 40.2 | 25.3 | 32.2 | 41.7 | 37.6 | 23.1 | 30.9 |
| Home | 33.3 | 27.0 | 42.9 | 32.9 | 36.1 | 26.4 | 33.7 | 35.3 |

¹ Represents approximately 10 per cent of deaths occurring in the selected states in 1941; excludes immediate deaths due to external causes and deaths in miscellaneous places (other than home and hospital).

² Definitions of "types of attendance":

"Without any attendance": deceased was not attended by a physician during terminal illness and no physician was present at time of death. If in a hospital, death occurred before medical attendance could be given.

"Without recent attendance": certifying physician had attended deceased in the past but had not seen him alive on the day of death or on the preceding day.

"Pre-death attendance only": certifying physician attended deceased only on the day of death or on the preceding day.

"Routine attendance": certifying physician attended deceased on day of death (or preceding day) and for at least 2 days before death.

³ Weighted by the total number of deaths occurring in each state reduced, for "immediate external" deaths and deaths in "miscellaneous places," by the same proportion as in the sample for each state.

⁴ Includes all hospital deaths certified by coroners.

⁵ Since all deaths in hospitals and institutions occurring within 24 hours after admission have to be certified by a medical examiner, a distinction between hospital deaths "with pre-death attendance only" and "without any attendance" is not possible.

the deaths in the sample for each state.

For the seven states, slightly less than 10 per cent were reported as without any attendance, slightly over 10 per cent as without recent attendance, nearly 14 per cent as with pre-death attendance only, and approximately 66 per cent as with routine attendance. As may be seen from Table 1, there is considerable variation among the states. For instance, for deaths without any attendance, the per cent varied from 6.5 in New Jersey to 19.2 in Arkansas. Deaths without recent attendance varied from 3.6 to 14.1 per cent, with New Jersey again the low state and Arkansas the high. Missouri showed the lowest proportion of deaths with pre-death attendance only, and North Dakota had the highest proportion.

States, such as New Jersey, which

showed a low proportion of deaths with limited amount of medical attendance (the first three categories) obviously would show a comparatively high proportion of deaths with routine attendance.

HOSPITAL AND HOME DEATHS

For the seven states, approximately 38 per cent of the deaths occurred in hospitals and 62 per cent at home. The proportion of hospital deaths varied

| | Hospital | Home |
|--------------------|----------|------|
| Arkansas | 22.6 | 77.4 |
| Colorado | 48.5 | 51.5 |
| Indiana | 31.0 | 69.0 |
| Missouri | 38.5 | 61.5 |
| New Jersey | 50.3 | 49.7 |
| North Dakota | 46.8 | 53.2 |
| Virginia | 29.2 | 70.8 |
| Average | 37.6 | 62.4 |

from less than 23 per cent in Arkansas to more than 50 per cent in New

| New Jersey | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Hospital | 85.6 | 75.9 | 53.6 | 40.4 | 33.5 | 27.7 |
| Home | 14.4 | 24.1 | 46.4 | 59.6 | 66.5 | 72.3 |
| North Dakota | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Hospital | 57.3 | 76.0 | 57.4 | 41.3 | 30.0 | 21.1 |
| Home | 42.7 | 24.0 | 42.6 | 58.7 | 70.0 | 78.9 |
| Virginia | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Hospital | 31.6 | 51.7 | 30.2 | 25.9 | 13.2 | 11.3 |
| Home | 68.4 | 48.3 | 69.8 | 74.1 | 86.8 | 88.7 |

Jersey. To some extent, these figures probably reflect the extent of hospital facilities available in the states.* For the seven states, 31 per cent of the deaths had routine attendance in hospitals. The three states of Arkansas, Indiana, and Virginia had less than this average, while New Jersey had 42 per cent of the deaths in this category.

As would be expected, very few of the hospital deaths were classified as without any attendance, although an average of 1 per cent of the deaths were emergency cases that died before any medical attendance could be provided.

The unattended home deaths constituted 8.5 per cent of the total deaths for the seven states. Missouri had 6.3 and Arkansas 18.0 per cent in this group.

The proportion of hospital and home deaths by age varied considerably among the seven states. In Arkansas

and Virginia, for example, there was a higher proportion of home deaths in each age group. In Colorado, New Jersey, and North Dakota there was a higher proportion of hospital deaths in the three age groups under age 65. In Indiana and Missouri there was a higher proportion of hospital deaths under age 45 and a higher proportion of home deaths for the age groups over age 45. (See Table 2.)

HOME DEATHS

The home deaths which, as shown in Table 1, constituted 62 per cent of all deaths in the sample, were analyzed in more detail in this study, since this is the group for which less information is available from other sources. For this part of the analysis, deaths of infants of less than 8 days of age were excluded. There was a total of 10,305 home deaths (out of 16,521) certificates used as the basis of the following analysis.

ATTENDANCE OF HOME DEATHS

Averages for the seven states,

* In 1941, the average number of beds in general and special hospitals exclusive of federal hospitals, per 1,000 population, was 1.6 for Arkansas, 3.8 for New Jersey, and 3.3 for the entire United States.

weighted by the number of deaths in each state, showed that 14 per cent of the home deaths were without any attendance during terminal illness, 18 per cent were without recent attendance, 12 per cent had pre-death attendance only, the remaining 56 per cent were classified as having routine attendance.

HOME DEATHS BY TYPE OF ATTENDANCE IN DIFFERENT SIZE COMMUNITIES

The average per cent of home deaths in each of the four attendance categories showed varied relationships to the size of the community in which the deaths occurred. (See Table 3.)

The individual states show some marked variations from these overall averages, but space does not permit the discussion of these different patterns.

UNATTENDED HOME DEATHS BY AGE AND RACE

In this sample of 16,521 death certificates, there were 1,537 deaths which occurred at home without any medical attendance. The age-at-death distribution of these unattended home deaths compared with that for the 16,521 deaths indicates that in the unattended home deaths there was a somewhat larger proportion of deaths under age 65 years. (See Table 4.)

TABLE 3

Home Deaths by Type of Attendance and by Population Size of Community

| | Population Size | | | | |
|---------------------------|-----------------|----------------|---------------|--------------|-------------|
| | 100,000 or More | 25,000-100,000 | 10,000-25,000 | 2,500-10,000 | Rural Areas |
| Without any attendance | 15.6 | 13.6 | 11.3 | 12.5 | 13.3 |
| Without recent attendance | 11.3 | 12.8 | 14.9 | 16.7 | 21.9 |

| Sample | 16,521 | 100.0 | 8.6 | 12.4 | 27.9 | 23.1 | 20.5 |
| Unattended home deaths | 1,537 | 100.0 | 12.1 | 11.7 | 32.3 | 21.0 | 15.7 |

Although routine attendance did not vary widely among places of different size, there seemed to be an increasing proportion of deaths with this type of attendance as the size of place increases. Deaths without any attendance, however, constituted a slightly larger proportion of the home deaths in large cities than they did in rural areas. In the two smaller size city groups, the proportion is slightly smaller than in rural areas. Deaths without recent attendance vary inversely with size of place, being least in the largest size community and greatest in the rural areas.

Table 5 shows the percentage of all deaths in the sample that occurred at home without any attendance in each age group for each of the seven states. This table does not show any marked age specificity although there is some slight indication that these unattended home deaths were proportionately more frequent among middle-aged persons. In states where the unattended home deaths were comparatively frequent (Arkansas and Virginia), there were peaks at both ends of the age range, although the peak for ages under 15 in Arkansas appeared to be due to the distribution of the Negro deaths.

TABLE 5

Unattended Home Deaths per 100 Deaths in Each Age Group, Each of the Seven Selected States (Distribution by Race for Three of the Selected States)

| State | Unattended Home Deaths per 100 Deaths | Unattended Home Deaths per 100 Deaths in Specified Age Group | | | | | |
|---------------|---------------------------------------|--|-------|-------|-------|-------|-------------|
| | | Under 15 | 15-44 | 45-64 | 65-74 | 75-84 | 85 and over |
| Arkansas | 17.6 | 19.7 | 14.7 | 18.6 | 17.0 | 16.7 | 22.8 |
| White persons | 15.5 | 13.9 | 15.4 | 17.2 | 13.5 | 16.1 | 19.1 |
| Negroes | 22.1 | 31.4 | 14.0 | 21.3 | 28.1 | 20.0 | 34.3 |
| Colorado | 8.4 | 14.6 | 3.6 | 9.8 | 9.2 | 6.1 | 7.9 |
| Indiana | 7.1 | 4.8 | 11.0 | 9.5 | 6.9 | 4.6 | 3.7 |
| Missouri | 6.2 | 5.3 | 6.9 | 7.8 | 6.0 | 5.0 | 5.1 |
| White persons | 5.8 | 4.5 | 6.0 | 7.2 | 5.7 | 5.0 | 5.4 |
| Negroes | 9.4 | 10.0 | 9.9 | 11.3 | 9.6 | 3.6 | ... |
| New Jersey | 6.0 | 5.1 | 5.5 | 7.5 | 5.3 | 5.6 | 4.3 |
| North Dakota | 7.6 | 7.2 | 7.7 | 8.3 | 7.1 | 6.3 | 10.3 |
| Virginia | 10.7 | 18.0 | 6.8 | 11.4 | 7.8 | 9.0 | 15.6 |
| White persons | 9.5 | 16.6 | 4.6 | 11.2 | 7.0 | 7.9 | 12.3 |
| Negroes | 13.2 | 20.2 | 9.9 | 11.7 | 10.1 | 13.8 | 28.6 |

CANCER DEATHS

No mention has been made up to this point, of the cause of death information on the death certificates studied. Of the few special, although limited analyses, the data on cancer deaths may be summarized as follows:

Analysis of the 1,953 deaths ascribed to cancer (Table 6) showed that 38 per cent occurred in hospitals and 62 per cent at home. For many cancer patients, care at home may, during the terminal phase of their disease, be as adequate as in a hospital. Slightly more than half of the persons dying at

ages under 45 died in hospitals. In each of the older age groups a higher proportion died at home than in hospitals.

For 79 per cent of the cancer deaths, the type of medical attendance was classified as routine. (Table 1 showed 66 per cent in this category for the sample as a whole.) The proportion with no attendance or with pre-death attendance only was slightly less than 7 per cent. Of the cancer deaths which occurred at home, 8 per cent had either no attendance or had pre-death attendance only, and 23 per cent were without recent attendance.

TABLE 6

Cancer Deaths by Place of Death and by Age of Deceased

| | No. | All Ages | Under 45 | 45-64 | 65-74 | 75-84 | 85 and over |
|----------------|-------|----------|----------|-------|-------|-------|-------------|
| 7 states | 1,953 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Hospital | 745 | 38.1 | 51.1 | 43.8 | 34.9 | 25.0 | 22.4 |
| Home and other | 1,208 | 61.9 | 48.9 | 56.2 | 65.1 | 75.0 | 77.6 |

TABLE 7

Cancer Deaths by Place of Death and by Type of Attendance

| | All Types of Attendance | Without Any Attendance | Without Recent Attendance | Pre-Death Attendance Only | Routine Attendance |
|----------------|-------------------------|------------------------|---------------------------|---------------------------|--------------------|
| 7 states | 100.0 | 2.5 | 14.3 | 4.4 | 78.8 |
| Hospital | 100.0 | 1.2 | | 3.8 | 95.0 |
| Home and other | 100.0 | 3.2 | 23.2 | 4.8 | 68.8 |

Theoretical Considerations Concerning Caries Control*

L. S. FOSDICK, PH.D.

Professor of Chemistry, Northwestern University Dental School, Chicago, Ill.

AT present there seems to be considerable confusion in the dental profession regarding the best methods for caries control. Some groups advocate control of dental caries through adequate diets,¹ but many groups living on inadequate or semi-starvation diets are relatively caries-free.²⁻⁵ Some groups feel that the best method of caries control is to eliminate carbohydrates from the diet,⁶ and some success has been obtained through this method, although there are large groups of people who consume large quantities of carbohydrates and are relatively caries-free. Other individuals feel that the application of various drugs, such as the fluorides, urea, zephrene and certain enzyme inhibitors may be the most effective means of controlling dental caries,⁸⁻¹¹ but there is still considerable skepticism concerning these methods.

It would be folly to assume that the many controlled experiments concerning the above methods of treatment were in error or that the startling exceptions to the results of any procedure were false. There must be some rational explanation for the conflicting results and opinions that are so prevalent today. At the present state of our knowledge concerning the chemistry of the teeth and saliva, and the mechanism of the formation of carious lesions, it should be possible to explain most of

the discrepancies and to predict the effectiveness of any control method when applied intelligently to any individual.

In 1937¹² it was shown that one fundamental difference between the salivas of caries-immune and caries-susceptible individuals was the rate at which acid would form from carbohydrates in the saliva mixtures. The saliva from susceptible individuals was found to degrade glucose to acid quite rapidly, while the saliva from immune individuals did not cause this fermentation to proceed very fast. About this same time it was suggested,¹³ and subsequently demonstrated,¹⁴ that the mechanism of acid formation in the mouth was identical or very similar to the normal anaerobic conversion of glycogen to lactic acid. This phenomenon occurs during the normal carbohydrate metabolism in muscle tissue and by practically all aciduric microorganisms.¹⁵⁻¹⁸ It would seem that this conversion is a universal metabolic process. The series of reactions has been intensely explored by numerous investigators, and it has been found that all reactions that take place during the process are enzymic in nature,¹⁹ and under optimum conditions each reaction is extremely rapid. (This series of reactions was formerly identified as the explosive conversion of glycogen to lactic acid.)

There is no reason to expect that under the conditions that exist in the mouth the reactions would be slow. However, it was not until Stephan²⁰ actually measured the rate of acid formation

* Presented before the Dental Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

in susceptible areas of the mouth that the significance of these reactions became clear. It was found that if the saliva was excluded from a susceptible area of the mouth,²¹ the acidity of that area would increase from around pH 6.0 to a pH of around 4 in as short a time as from 3 to 5 minutes, and that under normal conditions this phenomenon would frequently happen in areas in which saliva was not excluded. It was found that the average maximum acidity in the protected areas of the mouth would be reached at about 18 minutes after the applications of sugar, and that the acid potential would be sufficiently great to decalcify enamel²² for periods as long as from 30 to 90 minutes after the application of the sugar.

With the above information it was obvious that the carious process is not a long, continual, gradual, decalcification, but rather a series of intensive decalcifications. Every time a fermentable carbohydrate is ingested there is a very short but intensive attack of dental caries. Thus, if one eats sugar three times a day there would be three attacks, and if one eats sugar six times a day, there would be six individual attacks, providing, of course, that the oral environment was such that the acid would not be neutralized.

There have been many investigations of the composition and amounts of saliva produced, and from these data it is obvious that saliva is of variable composition and amounts.^{23, 24} However, in all cases saliva is a rather highly buffered medium, which becomes more alkaline upon stimulation. The very act of mastication of practically anything will normally cause an influx and a more copious supply of saliva and a more efficient buffering system. From these data it is clear that although acids are rapidly formed in some mouths the natural mechanism of controlling this acidity is the saliva. Practically all salivas will neutralize large quantities

of acids, but some salivas will neutralize more than others.

In view of the above it would seem that in the susceptible areas of the mouth there is a competition between the rate of acid formation and the rate of neutralization, and from an intensive investigation of these two variables²⁵ one should be able to explain the causes of caries and make an accurate prognosis.

If the acid is not neutralized, it will become neutralized by attacking the teeth to form calcium lactate. There are numerous variables which determine whether or not the acids which are formed in the protected spaces will be neutralized, such as the amount of saliva, the quality of the saliva, and the mechanical or anatomical features which are present in the mouth. If the teeth are so arranged in the mouth that there are inaccessible spaces, the saliva, no matter how copious, cannot penetrate these areas, and hence affords no protection against decalcification. Furthermore, the so-called bacteria plaque forms a very excellent mechanical barrier that will not readily be penetrated by the neutralizing influences of the saliva. For this reason, whether or not the acids that are formed are neutralized depends not only upon the quality of saliva, which in turn is controlled by diet, but also upon the many variables which may occur from mouth to mouth.

Most of the conflicting opinions concerning the various prevalent theories of the cause and control of dental caries can be satisfied by the following summary.

Dental caries is caused by an intermittent acid decalcification of the teeth. All of the acid is derived from carbohydrate that is left in the mouth after it is ingested and is not in any way related to that portion that is swallowed. In most cases the carbohydrate must be a fermentable one such as glucose or sucrose, but in those cases when there

is a high ptyalin activity acids may also be derived from starches. Whether or not the acids are harmful depends on whether or not they are neutralized before decalcification of the teeth occurs. This in turn depends upon the rate of acid formation and the rate of neutralization. The rate of acid formation depends upon the substrate and enzyme system. The rate of neutralization depends upon a multitude of variables such as amount of saliva, quality of saliva, and accessibility of the acid to the saliva. Some of the variables, such as the quality of the saliva, depend upon the diet and nutrition and can be controlled. But others such as amount of saliva may depend upon the state of the sympathetic nervous system, while others, such as the form, occlusion, and shape of the teeth depend to a large extent on heredity. Still others such as the bacterial plaque and certain protein constituents of the saliva are still very incompletely understood and the controlling factors in these cases are not known.

On the basis of the above, an adequate alkaline ash diet should decrease caries activity in many cases, due to a better quality of saliva. A starvation sugar-free diet should reduce caries because of the absence of a substrate and no protective action afforded by a well balanced diet is needed.

Some individuals naturally can tolerate large quantities of sugar, either because little of it is retained in the mouth or because the neutralizing system is sufficiently efficient, but on the whole a restriction of sugar should decrease the substrate. The use of enzyme inhibitors should reduce acid formation even in the presence of sugars and hence should produce effective control.

In view of this situation, it is obvious that in order to control dental caries, one must either inhibit the formation of acids or must make it possible for the saliva to neutralize them before dam-

age can result. The best method of approach will depend on the situation which presents in each individual mouth. Excessive acidity may be the result of excessive ingestions of carbohydrates or excessive retention of the carbohydrates that are ingested.

Very few individuals will restrict the carbohydrate intake to an extremely low level, and even then in some cases it is questionable whether positive results can be obtained. It may be that the major portion of ingested carbohydrates will lodge in the inaccessible areas of the mouth and be as harmful as large quantities of ingested carbohydrates in the self-cleansing mouth. This situation can be met by the application of enzyme inhibitors, but even here there is some question of maintaining a concentration of enzyme inhibitors in these areas during the time that acids are formed. At present the only enzyme inhibitor that is retained for appreciable periods of time is the fluoride ion, and this action is not purely inhibition but also a change in enamel solubility. All of the other enzyme inhibitors, of which there are several dozen, must be applied during the ingestion of the food or immediately thereafter. This presents a problem which is difficult to overcome, as very few individuals will take the time to introduce the enzyme inhibitor into the mouth.

A well balanced alkaline ash diet will provide more alkaline saliva, but if the occlusion of the teeth is unfavorable, and if the occurrences of pits and fissures are too numerous so that the saliva does not reach these areas, then the more alkaline saliva will be useless. This explains why some individuals respond to this treatment while others do not. Under these conditions it is practically impossible to control caries at present by any practical means with the possible exception of the topical application of the fluoride ion.

When one reviews the whole situation

it seems that at present no method of caries control is adequate for a large number of our population, not because it is impossible to find means of control, but because of the lack of coöperation of the individual. The methods of control which may succeed are so cumbersome that the individual would rather have rampant caries.

The application of fluoride to drinking water was one major step for the control of caries, because under these conditions the individual is applying an enzyme inhibitor constantly and with no additional effort on his part, but the fluoride ion is not an ideal enzyme inhibitor. It is too toxic to apply in sufficient concentrations to stop all acid formation, and all we can expect from it is simply a slight inhibition. It is quite possible, however, that a 10 per cent inhibition of acid formation will prevent 60 to 90 per cent of the caries, as it is only necessary to slow down the process of acid formation to the extent that the normal neutralizing influences in the mouth can cope with the situation.

A more ideal method would be to find an enzyme inhibitor that is not particularly toxic when ingested, or one that is destroyed by the G.I. tract. Under these conditions there would be no danger of inhibiting carbohydrate metabolism in muscle tissue, and sufficient quantities of the enzyme inhibitor could be utilized actually to stop acid formation. Furthermore, in so far as fermentable carbohydrates are the major substrates which can be utilized by the oral bacterial flora for acid production, some innocuous enzyme inhibitor could be placed in all fermentable sugars during the process of their manufacture. If some such substance could be found, then it would be possible to approach the problem from the purely public health standpoint. We should incorporate the enzyme inhibitor into the offending substrate and hence inhibit the major cause of dental caries. This

would be far superior to the fluoride ion because it would be approaching the problem at its source, and as everyone consumes fermentable carbohydrates, it would require no effort on the part of the individual and would protect those areas which do not use communal waters and under the present conditions cannot secure protection through fluorinated waters.

United States in World Health Organization

On June 14 the United States became the 42nd nation and the last of the Big Five to join the World Health Organization. On that day President Truman signed and deposited with UN Headquarters a joint Congressional resolution providing for United States membership. The Senate approved membership a year ago but House approval was bottled up in the Rules Committee until public pressure forced it out recently. France had deposited her ratification just previous to the United States action.

The House Bill, which approved United States membership in WHO, stipulates an annual limitation of U. S. contribution to WHO expenses of \$1,920,000, about 40 per cent of the agency's budget. It also provides that the U. S. representative on the Execu-

tive Board shall be appointed by the President with the approval of the Senate, and that such representative must be a physician or surgeon with at least three years' practice.

Completion of membership steps came just in time for the United States to have full fledged representation at the organization's first World Health Assembly which opened in Geneva on June 24. The representatives appointed by the Secretary of State are Thomas Par- ran, M.D., recently retired as Surgeon General of the U. S. Public Health Service; Martha M. Eliot, M.D., President of the American Public Health Association, and Associate Chief of the U. S. Children's Bureau; and James R. Miller, M.D., Trustee of the American Medical Association.

Health Department Experience for School Health Coördinators in Washington

MARJORIE EASTABROOKS, M.S.P.H., F.A.P.H.A., AND
HOWARD LUNDY, DR.P.H., F.A.P.H.A.

*Supervisor of Health and Physical Education, State Office of Public Instruction;
and Head, Health Education Section, Washington State Department
of Health, Seattle, Wash.*

The School Health Coördinator

The chief functions of the school health coördinator are to develop and coördinate the entire school health program and to relate it to that of the community. Experience has also shown this individual to be an excellent resource person for busy teachers and an equally valuable ally of the school administrator in relieving him of many of the details connected with the development of the school health program.

The majority of coördinators in Washington are health and physical education majors, and the time allocated for coördination varies from one period a day to a full-time position. In most cases these individuals have had no additional training for the work except attendance at several workshops and short courses.

Specific duties of the coördinator include the following:

1. Presenting to the administrator for his consideration any measures which may be needed to bring the school health program up to currently accepted standards of adequacy and quality.

2. Representing the school administrator at health committee meetings in the school and at community health meetings such as community health councils.

3. Helping to secure an integrated and func-

tional program of health teaching suited to the needs of all children.

4. Working with committees and with individual teachers on revisions of the health curriculum.

5. Securing background materials in health for use by teachers and students.

6. Securing audio-visual aids on health topics and assisting in their use.

7. Assisting in arranging for student field trips on health and for student participation in community health projects.

8. Securing speakers and community resource experts in the health field for all teachers.

9. Assisting in the conducting of workshops in health education.

The number of school health coördinators is steadily increasing in Washington. Where interested and qualified coördinators are employed, advancement of the school health program has been so marked that the State Office of Public Instruction has designated health coördination as one of the special service units for which extra reimbursement is available from the state.

Planning the Experience

The Joint Committee on the School Health Program, composed of representatives from the State Office of Public Instruction and the State Department

of Health, meets periodically to discuss and suggest policies and procedures which might be of assistance in developing local programs. One of its projects has been the formation of a plan whereby six selected school health coördinators received actual work experience in their local health departments during the summer of 1947.

The project was financed by the State Health Department through the use of maternal and child health funds from the Children's Bureau. Each coördinator received \$50 per week or \$300 for the six weeks of the experiment.

In each of the participating health departments, a supervisor was appointed who was responsible for planning the schedule, for introducing the coördinator to the staff, and for facilitating the project in general. This supervisor was either a public health nurse or a public health educator. The Joint Committee felt that this close supervision was essential if the plan were to succeed. Supervision from the state level was the responsibility of the authors.

Selection of coördinators

An announcement of this opportunity for coördinators was sent by the State Superintendent of Public Instruction to school administrators in the state, so that all interested coördinators could ask for consideration. At the same time local health departments were consulted by the State Department of Health as to their willingness and ability to coöperate in the project.

Applications were received from 31 coördinators, with varied backgrounds of experience and training. In selecting the six coördinators for the project, an effort was made to secure variety in the factors mentioned, and consideration was given to the likelihood of real development in their school health programs. School systems represented by the six ranged from a rural consolidated district to that of a large metropolitan

city. With one exception each coördinator was placed in the health department in his own locality.

The General Plan

As soon as the coördinators and the participating health departments had been selected, mimeographed outlines were distributed to both groups describing the nature of the experience desired, suggesting a general schedule which might provide such experience, and calling a meeting of all coördinators and supervisors in the office of the State Health Department.

This conference preceding the actual work experience secured a common understanding and established a feeling of unity on the part of all participants. It also facilitated the arrangement of slight deviations from the general plan which are always found necessary in individual cases.

Each coördinator spent a total of four weeks in the local health department and two weeks attending the intensive short course in health education given at the University of Washington by Dr. Dorothy B. Nyswander. In most cases, the schedule called for two weeks in the health unit, two weeks at the university and then a final two weeks back in the health unit.

A brief report of the experience was required from each coördinator and supervisor. These reports aided greatly in the evaluation of the project. In addition, one or more supervisory visits by the authors also assisted in the evaluation process.

Types of Experience

The following are examples of the types of experience obtained by coördinators through this project:

I. Conferences

A. In the health department

1. Individual, such as with nurses, sanitarians, and the health officer
2. Group, such as with the nursing

ference at a number of schools not participating in the project.

C. Values to the health departments

1. Since the coördinator presented the teacher's point of view, the entire health department staff gained a deeper appreciation of the school's problems and attitudes. Reasons for the success or failure of specific procedures were often brought out and a more democratic approach will undoubtedly result in the future.
2. The initiative for health projects will now come from within the school in many cases, instead of the health department attempting to superimpose them upon the schools.
3. The health department now has a person in the schools who understands the resources, problems, and attitudes of the health unit.
4. The project proved sound from a public relations standpoint since an influential member of the community has become a firm supporter through obtaining a close acquaintance with the personnel, program, and needs of the unit.
5. In several areas the coördinators are planning "orientation visits" to the schools for some of the staff of the health unit. The project will thus enlarge to a two-way affair.

Reactions of Participants

All six coördinators, all six supervisors, and the two authors are unanimous in recommending the project be continued and expanded next summer. The following are sample comments taken from the reports of the participants:

Coördinators

"I know that I have never spent a comparable time in an educational venture which I felt netted me so much."

"The practical, informal, individual type of learning experiences produced unusually satisfying results."

"I read more material during this six weeks than I ever did on a course in my life."

"Time will tell, but I am confident that results will prove that it was the most valu-

able thing we have done to accomplish a coördinated community health program with the school."

"I know it will be a great asset to me in the health instruction program."

Supervisors

"As a result of this six weeks' experience, I am an enthusiastic advocate of training more health coördinators. We would like to see a health coördinator in every school in County."

"I believe that if there could be more of such projects, the gap between the health department and the school would be greatly decreased."

"We would like to recommend that the State Department of Health and State Office of Public Instruction continue this program on a larger scale."

CONCLUSIONS

1. The school health coördinator is a key figure in developing an adequate school-community health program.

2. It is well worth the staff time consumed to bring the coördinator into the health department during the summer months in order to gain first hand knowledge of the personnel and services of the unit, and to plan jointly for the school health program.

3. Close supervision from the local level is essential to the success of the project and state supervision is desirable. The "suggested guide" prepared on the state level is a valuable aid in organizing the experience.

4. The project has proved so valuable and was received with such enthusiasm on the local level that it is planned to continue and expand it next summer. It is hoped that more health departments will participate and that two coördinators instead of one will visit each health department.

5. Since joint planning for a specific school health program was one of the most valuable features of the project, it is recommended that the coördinator work only in the health unit which serves his school.

6. The intensive short course in health education given at the University of Washington added greatly to the value of the project.

7. The possibility of granting academic credit instead of financial remuneration for such experience should be explored.

FIGURE 1⁸—Relative Population Trends of Fringe Area Around City Compared to Rest of County, 1920–1940.

sions, and other land uses—chosen for their relation to problems of environmental health. The population of the suburban area thus defined was approximately 21,000, with a density of 1,300 per sq. mi.

The community's environmental health status may be divided into three major categories: physical facilities, services, and administration.

PHYSICAL FACILITIES

Water Supply—

a. The city-owned water supply conforms to State Health Department quality standards but is inadequate in quantity to satisfy the current demand. The department of public works, responsible for the water supply, is considering development of a new source, which may entail an expenditure of some 18 million dollars. Numerous private supplies are in use, partly because city water summer temperatures reach 76°F. Increasing industrial demands rather than population growth are responsible for the shortage. A city policy of long standing opposes any plan to serve contiguous unincorporated areas, and the expansion plans now under consideration contemplate no change in this pol-

icy, although water mains are adequate, in most cases, to supply the populous areas adjoining the city. Anticipation of future demands is limited to growth within the corporate city limits.

b. Uncontrolled speculative development during previous boom periods accounts for the anomaly of thousands of vacant subdivided lots served by water mains (sufficient to accommodate housing for the entire county 1940 population in single family dwellings), while approximately 5,000 city residents occupy homes located in unserved areas. The city has been unnecessarily burdened with the cost of unused extensions, and the widely scattered houses that have been constructed in remote developments impose a disproportionate maintenance and operating cost on the water department.

c. Collaboration between the city health and water departments has been ineffective, despite excellent professional relationships. The health department is rarely consulted in matters of main extensions, improvements, installation of cross-connections, and similar problems. No sampling is conducted by the health department.

d. Almost one-half the population of the suburban area included in this study is included in two water districts. The economic difficulties that so frequently harass such projects, serving small residential developments, are evident in these cases. Inadequate financing forestalls the construction of lines to serve some 25 per cent of the population included in the corporate districts. Moreover, while water rates are comparable to city rates, the district supply is untreated well water with a hardness of 170 p.p.m., as compared to 85 p.p.m. for the softened city supply. The districts levy an additional tax for hydrant rental. When it is considered that city water revenue sustains the cost of operation of the sewage treatment plant, it is obvious that there is a marked dis-

programs designed to improve plumbing and sewerage facilities.

b. The principal watercourse in the community provides insufficient dilution to assimilate the sewage load satisfactorily. Treatment plant effluent, with 85 per cent of B. O. D. removed, occasionally equals twice the stream flow. Untreated industrial wastes are estimated to equal the plant effluent volume. Tributary drainage courses contribute an unknown quantity of wastes from private septic tanks and cesspools. The feasibility of small community treatment plants to serve outlying developments is severely handicapped by the lack of dilution available.

c. As in the case of water supply, city policy prevents the use of city sewers by non-residents. Within the city, sewers have been extended to subdivisions containing many thousands of vacant lots and a few scattered houses.

d. There are no public sanitary sewers in the metropolitan area outside the city. Effluent from individual treatment installations pollutes open drains and ditches, which course the city from all sides. The resulting nuisance conditions are serious blighting influences, in addition to the hazard created by gross pollution of a surface reservoir which serves as an emergency water supply. Efforts to solve this problem have lacked concerted support and have been fruitless.

e. City and county health departments exercise rigid control over the construction of new septic tanks by a combination of licensing, permits, and inspection. Effective as this measure has proved, it falls far short of achieving the needed solution.

Housing—

a. Based on the combined indices of overcrowding, need of major repairs, and lack of private bath, public health problems existed in 15 of 41 census tracts, when overall city averages were

taken as standards.¹ Of these 15 problem tracts, 8 are along the city limits and consist of sparsely developed subdivisions. All of the 7 remaining problem tracts include or adjoin industrial areas (see Figure 2). There were only three tracts fulfilling the combined conditions of more-than-average new construction, less-than-average density, and fringe location, which did not show definite excesses over averages in the three indices of housing problems.

b. A partial explanation for the choice of suburban homesites by the majority of new home owners during recent years may be found in the picture of outlying residential areas within the city, possessing many natural attractions, but permitted to become prematurely blighted. The progress of blight, and its associated substandard health conditions, has been accelerated by at least 20 years in the newer residential sections, as compared with tracts containing older structures, if census data on housing conditions can be taken as a crude measure of blight.

c. Contributing to the impairment of the otherwise desirable marginal locations were two particular circumstances associated with periods of critical deficiency of the housing supply: first, the policy which permits subdivision development without requiring the installation of public water and sewers, illustrated by the fact that the principal sectors lacking water and sewer lines are in six of the fringe census tracts with above average incidence of substandard conditions; and second, a relaxation of building code requirements to permit substandard construction, until in 1938 over one-seventh of all dwelling units were of the so-called garage type, located on the rear of the lots in anticipation of constructing a conventional type home at some future date.

d. Speculative overdevelopment has not been limited to the city proper, as

Many of the existing ills of this metropolitan community previously recounted can be ascribed to the rapid growth and accompanying decentralization that transpired prior to the establishment of the planning and zoning commissions. At the time this study was made (1946-1947), the city did not have a master plan, the zoning plan and regulations were obsolete, and subdivision regulations enacted in 1944 failed to provide for health department approval of plans. A recent instance illustrates the need for coordination of interests in the drafting and administration of such controls. A subdivision of 100 homes was well under construction, having been approved by the Planning Commission (without consultation with the health department), on the basis of individual or community private wells as the source of water supply and individual septic tanks for sewage disposal. Fortunately, an existing ordinance requiring health department permits for the construction of such facilities brought the developer to the health department, where he was informed that shallow wells could not be depended upon for safe water, and septic tanks could not function satisfactorily at the location in question. The builder was forced to arrange financing to provide city water and sanitary sewers, necessitating a sewage lift station, through no fault of his own. It is entirely possible that earlier knowledge of this exigency, to which he should have been entitled, might have prompted the choice of a site better located and already served by utilities, rather than the isolated, inconvenient location approved by the Planning Commission.

The construction of 322 septic tanks in the city during the preceding 5 years, while thousands of lots improved with public sewers remain vacant, attests again to the environmental health implications of planning and related services.

b. The townships encircling the city were without any planning, zoning, or subdivision controls. State enabling legislation authorizing local adoption of such programs had been enacted in 1943, and civic groups have been debating the possibility of local application. These townships have been experiencing the mistakes resulting from rapid unplanned growth that have afflicted the city in former years. Trailer camps, industries, and undesirable commercial establishments may be noted adjacent to otherwise desirable residential sections in the fringe area. This situation handicaps the efforts of the health department to obtain the badly needed environmental improvements, for it contributes to the despoiling of neighborhoods as permanent homesites, resulting in occupancy by a mobile population lacking in civic consciousness.

c. Housing, building, and plumbing codes are vital services in urban areas, of recognized import in the maintenance of a healthful community environment.² Communities which permit the construction of substandard dwellings, lacking essential sanitary provisions, are burdening the health department with a difficult and often hopeless task, for in congested areas these conditions become problems affecting the entire neighborhood, demanding corrective measures.

The high proportion of garage-type houses, basement houses, shacks, converted house trailers and similar dwellings, both within and outside the city in this metropolitan community testify to the failure of governmental services that might have precluded or modified this problem.

ADMINISTRATIVE PROBLEMS

a. Separate city and county health departments serving one metropolitan community always produce jurisdictional difficulties, but when large numbers of the populace of the central city

spill over or migrate to the suburbs the administrative difficulties of both are substantially augmented. In this instance further complications existed because of the numerous independent units of government in the county, and in addition, several environmental health activities were the legal responsibility of various state agencies.

The environmental health sections of both health departments were directed by competent, well trained sanitarians, who have developed superior programs in some fields and have endeavored to coordinate policies and programs. But the lack of qualified public health engineering personnel on the staffs was manifest by the impotence of the approach to some of the major problems of engineering character, such as sanitary utilities and subdivision controls.

b. There was no regional or county planning authority or other agency to coordinate attempts to solve environmental problems affecting both the city and county. The city housing, planning, and zoning programs had not progressed to the stage of positive, overall action necessary to correct past ills and prevent future mistakes. Much of the enforcement activity was limited to complaint investigation. The townships adjoining the city had just begun to consider the need for planning, subdivision controls, building codes, and related services.

c. The pronounced lack of coordination of the many programs and policies bearing upon the community's environmental health status is an administrative obstacle common to the larger cities. Communities suffering with a decided decentralization movement face the added task of harmonizing the efforts of various governmental units outside the central city. Such was the situation in the metropolitan community subjected to this study. The city had made little progress in the integration of policies and activities relating

to common problems, and was greatly handicapped with respect to suburban areas by the almost total lack of comparable services maintained in the county.

Neither the official city planner nor the city health department has been consulted in regard to the extensive improvement program contemplated for the water supply. Sewerage problems similarly were resolved by the public works department, with little participation by the health department except where lateral extensions were sought by the health department to correct insanitary conditions. Review of subdivision plans for water supply and sewerage was the exclusive responsibility of the public works agency. Garbage collection and disposal was another function of the public works department, conducted without the counsel of other units. Contrasting with such marked independence of action and policy, the building, plumbing, zoning, and housing inspection services performed by the department of public works demonstrated the possibility of coordinating programs of mutual concern to several official agencies. The widespread conditions of impending blight in this comparatively young metropolitan community require aggressive measures, with the collaboration of all agencies that can contribute to the rehabilitation of such conditions.

d. The city planning, zoning, and housing commissions, responsible for the administration of programs demanding the utmost degree of collaboration and integration with all units of government, were found to be functioning in an almost sequestered fashion. This practice was particularly noticeable with respect to health department relations. The planning commission membership did include the public works director, but provided for no functional committees with representative members from the numerous agencies concerned with the diverse facets of planning.

Consideration of environmental health cannot logically ignore the many health problems associated with blight, poor housing, overcrowding, atmospheric pollution, and similar conditions which planning and zoning purport to control and improve. Numerous studies have shown how blighted and slum areas become an economic liability, producing reductions in tax revenue and requiring increased municipal services, including public health.³ It is difficult to reconcile these known facts with the reported limited interest in the initiation of vigorous preventive and corrective measures to combat the decentralization movement. The tendency for specialization in governmental administration has frequently been overemphasized, and the ensuing confusion or misunderstanding is responsible for charges of inefficiency, extravagance, partiality, and prejudice.

An outstanding but not unusual illustration of the environmental health implications of zoning has been mentioned previously. The seven census tracts adjoining or including industrial establishments had a higher incidence of environmental health deficiencies than the city average, whereas other tracts similar in such characteristics as density and average age of structures had a lower-than-average incidence of such defects. This picture, demonstrating the influence of proximity to commercial and industrial zones, shows the need for re-zoning that would afford reciprocal protection to both industrial and residential interests.

The obvious need for expanded water and sewer systems in this community raises the zoning question when the design stage is reached. Adequate zoning will prove valuable in defining the anticipated maximum demand for specific areas.

Building, subdivision, and housing controls might be designated as prophylactic measures, subordinate to and integrated with planning and zoning. It has been aptly stated⁴ that, "No sub-

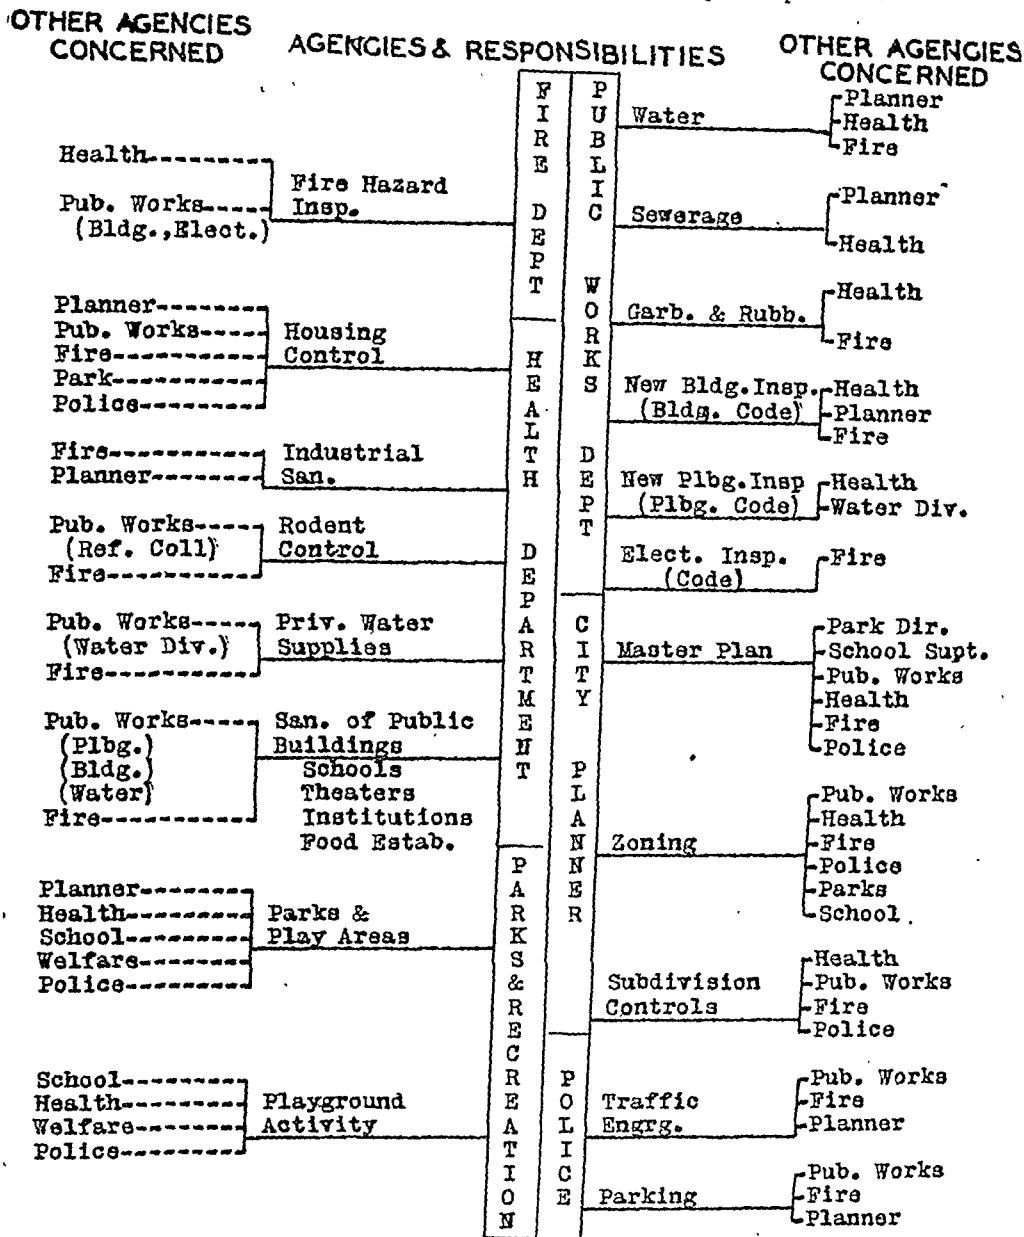

division can be sound, economically, unless it has all the improvements necessary to make home building a desirable investment. . . . Too often the innocent purchaser of a home finds himself faced with unforeseen heavy assessments for sewers and paving, which he is not financially prepared to meet. Furthermore, the cost of improvements in a neighborhood that is already built up will inevitably be higher than if the improvements had been provided at the outset." The critical substandard housing conditions in this community previously cited, lack of flush toilets, bath, running water, etc., constitute problems whose correction is a health department responsibility; but such conditions could have been *prevented* by good building, subdivision, and housing controls based on due consideration of environmental health.

The unincorporated fringe area, with its urban density of population, but without any pretense to urban facilities and controls, has already developed environmental conditions much worse than those in the city, with the health department efforts largely limited to the hopeless task of attempting to enforce general nuisance regulations designed for rural conditions.

CONCLUSIONS AND RECOMMENDATIONS

a. The conception of a metropolitan community as a single community, irrespective of political subdivisions, is essential to view its environmental health problems with an overall perspective. The health department as a service agency, typifies the possibilities of such treatment. As in this case, where separate departments serve the central city and its environs, it often has been extremely difficult to coordinate effectively even such well established and highly developed programs as milk and food sanitation. It is very doubtful that the much broader planning program, necessarily including

FIGURE 3—Interrelated Interests of Some Municipal Departments

many agencies within its scope, could be adequately developed in its environmental health phases when separate health jurisdictions are involved, and no metropolitan planning group exists.

An A.P.H.A. review of the public health program in this city and county in 1940 included a recommendation that the two health departments be combined. The solution of the environ-

mental health problems discussed in this report could be expedited in no small measure by such a step.

The employment of competent public health engineering personnel in responsible capacity should make possible increased emphasis on those environmental health problems of primarily engineering character.

b. Recognition of the hypothesis that

when extensive substandard environmental health conditions prevail in any section of a metropolitan community, they constitute a potential hazard to the entire community, will explain the necessity for coördinated planning and combined effort by the various agencies of all political subdivisions within the area.

The authors have attempted to show how pronounced decentralization trends within a typical metropolitan community have magnified the environmental health problems; how such problems relate to the responsibilities and activities of many governmental agencies; and the need for emphasis and initiative by the health department if other agencies are to give due consideration to the environmental health aspects of their programs. Observations reported here supply evidence of the importance of *preventive* measures in dealing with those causes of outward migration that involve environmental health conditions.

Figure 3 depicts the interrelated and overlapping interests of several municipal departments and suggests the possibility of an official committee as a means of effecting joint policies, eliminating duplication, and providing improved services. The expansion of such a committee to include comparable representation from the suburban areas would assure a broader perspective of mutual problems.

c. The similarity of environmental problems confronting the city and the populous suburban community presents an opportunity for health department participation in their solution, that could go far toward averting a repetition of past mistakes and omissions largely responsible for the present pernicious effects of the decentralization trend. Among such problems are the following:

1. The need for an additional source of water supply to serve the city, and for the extension of the water distribution system to serve adjoining areas.
2. The necessary expansion of the city sewage treatment plant, and the lack of sanitary sewers in the unincorporated fringe. Elimination of pollution of city streams.
3. Control of water supply cross-connections and abandoned wells.
4. The lack of any master plan in the community. Every effort should be made to approach this task as a metropolitan area problem. Public administration groups urge the use of a health committee in development of the master plan necessary for a wholesome environment.⁵ Specific public health interests in planning should include land uses, population density, types and location of industry, housing, water supply, sewerage, recreational facilities, zoning, subdivision control, community services, etc.
5. The need for re-zoning in the city and the lack of any zoning in the adjoining townships. The advantages of metropolitan zoning committees whose membership would include health authorities has been emphasized by Young.⁶ The health department can assist in the preparation of zoning plans and regulations, and, furthermore, can reinforce their application by review of applications for industrial and commercial establishments, investigation of appeal cases, and similar measures.
6. The city's subdivision regulations should be revised, and comparable regulations are needed in the adjacent townships. The need for adequate building, zoning, and subdivision regulations has been stressed by the private home building interests within the community.⁷ The health department is concerned not only with water supply and sewerage for new subdivisions, but to a large extent with surface drainage, grossly polluted open watercourses, atmospheric pollution, mosquito breeding places, rodent infestation, and other possible blighting influences.
7. The city-building and plumbing codes need revision, and similar controls are sorely needed for the suburban area. Enabling legislation is provided, and uniform codes are advocated by state authorities.
8. The need for a comprehensive housing program is urgent, for the entire metropolitan community. The diverse phases of the housing problem have contributed materially to the urban development outside corporate city boundaries. A thorough study of housing conditions could be valuable in the planning of the needed program. It is claimed that for the most part the residential communities in the unincorporated areas are a tax liability to the county, penalizing the farm population and precluding the provision of essential facilities and services.⁸

Increasing the Scope of School Sanitation Service in Local Department of Health Programs

S. D. STURKIE, M.D., M.P.H.

Director of Public Welfare and City Health Officer, Lynchburg, Va.

A TYPICAL program of school sanitation, such as is being carried out by the average county or city health department is markedly limited in scope when one considers the broad possibilities in that field of public health endeavor.

There have been two, and usually only two, components of the typical rural program in particular, namely, protection of school water supplies and installation of safe facilities for the disposal of excreta. With the inauguration of hot lunch programs, supervision of school cafeterias was added to the health department's program of school sanitation. In some rural localities, attention also has been given by health departments to handwashing and drinking facilities in schools. Lack of funds for the provision of an adequate number of approved facilities by school authorities has limited the health departments which have taken an interest in these facilities, to the development of improvised substitutes and recommendations for the best possible technique of handwashing in the absence of approved equipment.

The customary procedure in the typical program consists, initially, of an annual survey of the schools made by the county sanitation officer. In the survey an inspection is made of all school toilets. Determination is usually made of the adequacy of the number of toilet

seats based on a recommended standard. The state of repair of all pit privies and their compliance with state standards with regard to construction are usually noted. If there is a water carriage system of excreta disposal, an investigation is made of the disposal system. The school water supply and its source are carefully studied, including both sanitary inspection of the source and bacteriological examination of the water. A comprehensive report covering the entire system of schools is usually prepared and recommendations are listed for necessary improvements. The health officer submits a report of the survey to the school board which may or may not approve use of school funds by the superintendent to effect improvements.

As these basic requirements for the prevention of the spread of enteric diseases are met, an alert and efficient health officer will then focus his attention on other needs in the area of school sanitation. It is necessary for the health officer to have a concept of health which does not limit the meaning of that word to a state of being free from communicable disease. The adequacy of lighting, for example, in the classrooms, the corridors, the cloak rooms, and the toilets, is known to influence both physiologically and psychologically the individual school child. Proper lighting is necessary not only to

promote efficiency, but to prevent eye strain and impairment of vision.

It was the writer's experience four years ago to leave the field of county health work to become a city health officer. The southeastern city which was his new post had a population of 44,541, of which 34,305 are white and 10,236 are Negro. The official health agency of the community is the Bureau of Health of the Department of Public Welfare. The official title of the health officer is "Director of Public Welfare" since he is the head of the Department of Public Welfare. In practice, however, his chief duties are those of the health officer. In this city there are 20 schools, 14 white and 6 Negro. There is a school population of 7,299 and a total of 242 classrooms.

There had been no program of school sanitation in this community. The first step undertaken by the writer was to have a sanitary survey of the school cafeterias conducted. A report of the findings, with recommendations for improvements, was submitted to the superintendent and the school board with most gratifying results. Following the survey, routine periodic inspection of school cafeterias by a sanitarian of the Bureau of Health, was inaugurated.

With the objective of making a more substantial contribution to school sanitation in his city, the writer then conceived a plan to evaluate the entire school system, utilizing standards obtainable from a variety of sources. One of the best sources proved to be the well known public health textbook *Municipal and Rural Sanitation* by Ehlers and Steel. Other valuable sources were *The Minimum Requirements of the Virginia School Law* and the textbook *School Health Problems* by Chenoweth and Selkirk.

In the setting up of standards for use as a yardstick, it was decided that the policy would be to employ the highest standards obtainable, regardless of

source. What emerged finally, was a body of standards slightly higher on the whole, and to a degree, more complete than the minimum requirements of the Virginia School Law.

To arrive at a result that would have meaning and the fullest possible impact on community consciousness, it was decided that a rating was necessary. It occurred to the writer that the system of rating of dairies and milk plants used by the U. S. Public Health Service could serve as a useful instrument in this respect.

In attempting to apply this method of rating to a school system, however, he found himself in a quandary as to whether a different weight according to its sanitary and public health significance, or an equal weight should be assigned to each item of sanitation. Realizing that the former method was perhaps the more scientific, but suspecting that there might be a challenge either from the public or school authorities on the relative values of certain items, he elected to give all items an equal value.

There was also the question of whether to employ the practice adhered to in the U. S. Public Health Service rating system of giving credit for only items for which all requirements were met, or to give credit for each sub-item complied with. Here, again, it was decided that the policy which would evoke the least possible criticism of the survey should apply, and for that reason the decision was to give credit for compliance with sub-items. Two exceptions were made to this. In the case of "approved drinking fountain" and "system of ventilation" it was felt that all requirements should be met to justify credit for the item.

A rating was computed for each school and for the system as a whole. First, a weight was assigned to each sub-item equal to the average daily attendance.

A credit was given to each sub-item equal to the actual number of children served by equipment meeting the standard. The rating for each item was then computed by totaling the credits of the sub-items. The rating for the school was computed by dividing the sum of

the weights into the sum of the credits and multiplying the quotient by 100. A rating for the school system, as a whole, was computed in a like manner.

The items and sub-items used in the survey were as shown in the following chart.

SANITARY SURVEY OF SCHOOLS

Location of Building

1. Location, size of ground.
 - a. Streets paved
 - b. Isolation from factories
 - c. Isolation from railroads
 - d. 272 sq. ft. of play surface per child
 - e. Grounds used for community recreation

Building

1. Arrangement for optimum use of daylight
 - a. Corridors, stairway on one side; classrooms on the other
 - b. Windows face generally east or west
2. Design of Classrooms
 - a. Ratio of length to width between 0.6 and 0.7
 - b. Maximum length not more than 32 ft.
 - c. 15 sq. ft. of floor area per pupil
 - d. 200 cu. ft. of room volume per pupil
 - e. Maximum number of pupils per room not over 30

Toilet Equipment and Wash Bowls

1. Type of equipment
 - a. Individual seats
 - b. Individual urinals
 - c. U-shaped seats open in front
 - d. Non-absorbent seat material
 - e. Back siphonage proof
 - (1) Tank
 - (2) Bowl
2. Adequacy of equipment
 - a. 1 toilet seat for every 15 girls
 - b. 1 toilet seat for every 25 boys
 - c. 1 urinal for every 15 boys
 - d. Number of wash bowls equal to number of classrooms
 - e. 1 wash bowl near each toilet
 - f. Provision of toilet paper
 - g. Provision of towels
 - h. Provision of soap
 - i. Provision of receptacle
3. Maintenance of equipment
 - a. Urinals

- b. Toilet bowls
- c. Wash bowls

Toilet Rooms

1. General physical features
 - a. Floor of non-absorbent material
 - b. Adequate ventilation
 - c. Ratio of window to floor area of 1 to 12
2. Maintenance
 - a. Floors
 - b. Walls
 - c. Windows
3. Cleanliness
 - a. Floors
 - b. Walls
 - c. Windows

Drinking Facilities

1. Type of fountain
 - a. Diagonal jet
 - b. Guard
 - c. Orifice above rim of bowl
2. Number of fountains
 - a. 1 for each 50 children
 - b. 1 antifreeze fountain on playground

Seating

1. Type
 - a. Adjustable
 - b. Backs curved
2. Spacing
 - a. 30 in. distances between rows
 - b. 30 ft. maximum distance of any one seat from blackboard

Lighting of Classrooms

1. Natural Lighting
 - a. Ratio of window area to floor area of 1 to 5
 - b. Light source from the left
 - c. Windows not facing pupils
 - d. Windows not lower than 3½ ft. from floor and within 6 in. of ceiling
 - e. 2 shades per window

- f. Classroom walls of light color
- 2. Artificial lighting
 - a. Direct lighting enclosed or located at height of 20 ft.
 - b. Semi-indirect or indirect light with highly reflecting ceilings

Ventilation

- 1. Natural (approved for small schools only)
 - a. Windows open top and bottom
 - b. Bottom only and transom
- 2. Window ventilation and gravity exhaust
 - a. Radiators under windows
 - b. Window deflectors
 - c. Windows open at bottom
 - d. Exhaust duct
- 3. Artificial ventilation (Plenum System)
 - a. Each room governed by separate damper
 - b. Each room with small branch duct
 - c. Grills to lower velocity of entering air

Heating

- 1. Stove (approved for schools with less than 6 classrooms)
 - a. Jacketed stove
 - b. Fresh air duct
 - c. Exhaust duct
- 2. Central heating (required for schools with more than 6 classrooms)
 - a. Metal radiator shields
 - b. Radiators project not more than 15 in.
- 3. Temperature
 - a. Thermometer
 - b. Thermometer marked at 68°
 - c. Thermometer at desk level

- d. Temp. between 65 and 68° at desk level or otherwise 70°

Cleaning and Maintenance

- 1. Methods
 - a. Daily policing of building by principal
 - b. Systematic instruction of janitors
 - c. Wet sweeping of floor
 - d. Daily sweeping of floor
 - e. Wiping of furniture with oiled cloth
 - f. Daily wiping of furniture
 - g. Windows washed twice a school year
 - h. Light bulbs cleaned twice a school year
- 2. Maintenance of Classrooms
 - a. Floors
 - b. Blackboards
 - c. Desks
 - d. Windows
 - e. Lights
- 3. Cleanliness of Classrooms
 - a. Floors
 - b. Blackboards
 - c. Desks
 - d. Windows
 - e. Lights

Other Miscellaneous Items

- 1. Equipment
 - Ringworm Control *
 - a. Foot baths
 - b. Location at entrance to shower
- 2. Methods
 - a. Compulsory for all pupils

* Not included in computation of rating

When the *modus operandi* of the survey had been developed and the various record forms designed, the next step was to sell the project to the superintendent of schools and his assistant, the supervisor of school buildings. Their wholehearted cooperation was procured without difficulty.

The "leg" work of the survey was done by two general sanitarians, and a total of 275 man hours of working time were expended. The actual performance of the job by the sanitarians required a multiplicity of activities as shown in the following list which is not complete:

- 1. Measurements of the dimensions of each classroom and the window area in each classroom.
- 2. A general inspection of the premises of each school, including all corridors, classrooms, and toilets, noting the general cleanliness, the state of maintenance, and the cleanliness of the floors, the blackboards, the walls, and the windows; the type of design of the toilet seats, the urinals, the drinking fountains, and the pupils' seats.
- 3. A study of the facilities for ventilating and artificial lighting in each classroom.
- 4. Observation of the radiators and the temperature in each classroom.
- 5. Study of the general surroundings and the grounds to determine the area of the school grounds, the adequacy of drainage, the presence of paved streets.

6. Determination of the direction faced by classroom windows by the taking of compass readings.

7. A study of the methods of cleaning and maintenance with special reference to dust control and ringworm control.

The findings of the survey show that in a fairly typical southeastern city there is a prevalence of sanitary defects in the schools sufficient to justify efforts to promote their correction by the local department of health.

There is no reason, however, to suppose that this constitutes an amazing revelation to a majority of health officers.

The overall rating of 73.8 per cent of the Lynchburg school system, with ratings for individual schools ranging from 61.5 to 85 per cent, does at least give expression quantitatively to a fact which many health officers have only been aware of qualitatively with respect to their school systems.

Furthermore, as far as health officers in the southern states are concerned, it can be pointed out that these findings apply to a city located in a state in which the per pupil expenditure in the year 1942 exceeded those for seven other southeastern states. The inference from this is, of course, that if there are defects to the degree shown in the survey present in this situation, it is possible they exist to an equal degree, or even on a larger scale, in other cities, especially in the South.

In addition to pointing up the prevalence of sanitary defects in schools, the results of this survey have thrown some light on the practicableness of existing recommended standards for school sanitation.

The reader may draw his own conclusions with reference to this and other questions from the following summary of the important findings of the survey:

Location of Building—

1. Only 10 per cent of the school population attend schools with grounds providing

play surface in the amount of 272 sq. ft. per child. Since it is obviously difficult for city schools to comply with this standard, perhaps 100 sq. ft. per child would be a more practical standard.

2. Only 54 per cent of all school children attend schools with grounds used for community recreation.

Building—

1. No schools are arranged with corridors or stairway on one side and classrooms on the other. One wonders if this could be achieved without sacrificing space to a degree that would be prohibitive.

Toilet Equipment and Wash Bowls—

1. Only 25 per cent of the boy population is served with individual urinals. A majority of the schools still have trough urinals.

2. Twenty-two per cent of the school population is served with toilet seats that are not U-shaped and open in front.

3. Only 26 per cent of the total school population is served by equipment meeting the standard of one toilet seat for every 15 girls. Only 6 per cent have one wash bowl for every classroom; it is estimated that 100 wash bowls are needed in the entire system.

4. Thirty-five per cent of the school population is served by urinals and 37 per cent by toilet bowls that are not clean or in a satisfactory condition.

Drinking Facilities—

1. Only 53 per cent of the school population is served by approved drinking fountains; 41 per cent of all fountains are not of an approved type.

2. Forty per cent of the school population is served by an inadequate number of fountains; 58 per cent of the population has no outside fountain.

Seating—

1. Only 4 per cent of the school population has the recommended adjustable type of seating. None of the schools have the recommended 30 inch distance between rows of seats.

Lighting of Classrooms—

1. The requirements for both natural and artificial lighting are generally being met.

Ventilation—

1. Only 19 per cent of the school population is being served by approved ventilation facilities. The greatest lack is that of window deflectors as part of a window-gravity exhaust system. Deflectors are needed in 15 schools and exhaust ducts in 7 schools. A majority of

the schools now have only natural ventilation which is approved only for small schools. Nine schools have artificial systems which have been abandoned.

Central Heating—

1. Eighty-six per cent of the school population representing 18 schools do not have metal radiator shields to protect children who are seated close to radiators from overheating.

Temperature—

1. No schools have thermometers marked at 68° F., and only 2 per cent of the population have thermometers that are properly located at desk level.

Cleaning and Maintenance—

1. Wet sweeping of classroom floors is being practised in schools serving only 9 per cent of the school population. Janitors complain that the use of moistened sawdust or paper scraps is difficult in classrooms because of the tendency of particles of sawdust or paper to cling to the legs of seats.

Miscellaneous Items—

1. Only 7 per cent of the school population attend schools in which soap was found at the school on the day the survey was made.

2. Of the four schools with gymnasias, only one has showers. In this school, while an effort is being made at ringworm control, improper location of the footbaths and lack of supervising personnel makes the system only partly effective.

The report of the survey was received appreciatively by the superintendent of schools and the membership of the school board. The supervisor of buildings has been authorized to proceed with the necessary improvements as rap-

idly and completely as availability of funds and materials will permit. Immediate attention is to be given to the most glaring deficiencies such as provision of fountains for two Negro schools where the number of children per fountain was 104 and 148 respectively.

It is to be conceded that the final proof of the efficacy of this broadening of the school sanitation program depends upon effective action by the school authorities in the correction or elimination of the unsatisfactory conditions which were found. It remains, therefore, for the future to demonstrate the success or the futility of the action that has been taken.

Action, however, in this field, as far as this one local health agency is concerned, has only begun. A continuing program of inspection and promotion is planned for the future, and at the end of a five year period it is contemplated that the survey will be repeated to determine, if possible, the measure of the success or failure of the program.

In this paper, an attempt has been made to call the attention of local health authorities to the existence of areas in school sanitation which are perhaps being neglected on a wide scale, and to exhibit an approach to the broadening of the school sanitation program which, imperfect as it no doubt is, at least points up the many latent possibilities which prevail in improving the environment of the school child.

Proposed Report on the Educational Qualifications of Sanitarians^{*†}

I. GENERAL SCOPE OF THE FIELD

A. Sanitarians constitute the second largest group engaged in public health activities in official health departments. They are employed by state, county, and city health departments to carry out inspectional and educational duties, and to enforce laws in the field of environmental sanitation. Their work, more than that of any other group except public health nurses, brings them in close daily contact with the general public and consequently has great influence on the public's judgment of the entire department. The complexity of functions touches all phases of community life, draws upon knowledge of the physical, engineering, biological, and social sciences, and is interwoven in nearly all other activities of a complete public health service.

B. Future Outlook

The proposed expansion of public health departments throughout the country will increase the demands for personnel in environmental sanitation. This expansion applies to existing departments as well as to new units which

will be organized to give the nation complete coverage of local public health service.

Increased appreciation of sanitary conditions is apparent; not only are existing health departments receiving increased local and state budgets for this function, but industry and food handling establishments in particular are employing sanitarians.

The employment of qualified sanitation personnel at higher salaries by business concerns places increasing pressure on governmental agencies to meet this competition for personnel.

Among the many phases of the expanding program, attention is directed to the increase in jurisdiction over sanitary phases of housing in urban and non-urban areas. The expansion of the real estate sub-divisions in proximity to metropolitan areas will continue for many years with attendant sanitation problems to be dealt with by local health department employees.

Recent studies indicate that the present practice in the better local health units is to employ one sanitation worker to 16,000 population. This would indicate a need of 10,000 for the entire country.

The availability of qualified personnel is being increased by the veterans' educational program and the use of federal funds for the training of sanitation personnel. The development of higher standards of education for sanitarians is noticeable in announcements from public employment agencies. As standards are raised those sanitarians who have college

* The Committee on Professional Education of the American Public Health Association publishes this report before transmittal to the Governing Council in order to permit the members and Fellows of the Association to review it and to offer criticisms and suggestions in the further consideration of the report.

This report, like all other statements of the committee on professional and technical qualifications in public health, is subject to periodic revision in order that it may be kept abreast of the best thought.

† This proposed report is a revision of the Report on the Educational Qualifications of Sanitarians approved by the Governing Council on October 5, 1937, and is intended to supersede the earlier report.

degrees in the biological sciences and public health will have greater opportunity for advancement.

C. Lines of Promotional Progress

The lines of promotion vary in individual communities and states according to the administrative organization.

Ordinarily in a local health department the person without previous experience starts at the lowest grade unless qualified in special fields such as entomology or dairy industry.

He then advances by examination or merit to higher positions in the general or specialized fields. Promotions to supervisory positions are achieved only after years of experience and proven administrative ability. Some sanitarians may decide upon additional academic training so as to qualify as public health engineers, medical health officers, bacteriologists, or health educators.

For those working in state departments of public health advancement proceeds from the status of sanitarian in a district to the position of state-wide advisory sanitarian.

The following list indicates the lines of promotional progress:

1. Local

Assistant sanitarian

Sanitarian (Includes sanitarians specializing in food, industrial, housing, plant, and other phases of sanitation)

Supervising sanitarian

2. State

Sanitarians (District)

Advisory sanitarian

D. According to statistics published in *Local Health Units for the Nation* the number of sanitarians employed by local official agencies in the United States in 1942 was 4,927. However, there has been an increase in employment since the time these data were gathered. In one state the increase was approximately 25 per cent up to July, 1947.

E. The sanitarians mentioned in "D" are employed by state, county, and municipal health departments. However, increasing numbers are being employed by other official agencies and private industry. Sanitarians are employed as such in the U. S. Public Health Service and other governmental agencies; for example, food and drug divisions, dairy divisions of agricultural departments, housing divisions, rodent control divisions, mosquito abatement districts, prison boards, and institutions. Private industry is making use of sanitarians in a rapidly expanding field in food processing plants.

II. STATEMENT OF FUNCTIONS

A. Inclusive List of Duties Which May Be Performed by Sanitarians

1. Under the supervision of the health officer or public health engineer or other person designated by the health officer, the public health sanitarian carries out inspectional, educational, and investigational duties, and assists in the enforcement of the law in the field of environmental sanitation. His activities include assistance in the control of domestic water supply and sewage disposal; wastes disposal; swimming pools and recreational areas; dairies and milk handling plants; manufacturing, processing, storage, handling and distribution of foods; housing; industrial sanitation; school sanitation; rodents and insects and nuisances. He also participates in the inspection of institutions and assists in the control and epidemiological investigations of communicable diseases.
2. As a member of the team composed of the health officer, public health engineer, and other members of the health department staff, his responsibilities relating to the list of duties above include the conducting of surveys and the analysis of information obtained thereby; the determination of sanitation problems, education of the public in regard to them, and development of programs for solving them; the evaluation of laws and regulations and the formulation of recommendations for necessary changes and additions; assistance with the organization of community groups interested in sanitation programs, and the pro-

motion of sanitary practices through use of the various publicity media; study and research in the sciences and technics of public health for the increase of knowledge and a better understanding; and the administration of field and office work.

B. Classification of Grades *

To obtain a more accurate concept of the position of Sanitarian a general classification is necessary. Three grades of attainment are recognized: The highest or Supervisory Grade in which the individual is responsible to the health officer or the director of the environmental sanitation division for directing and administering a section of the environmental hygiene program; the Intermediate Grade, a position under the director of a division with responsibility for supervision of other sanitation personnel; and the Lowest Grade which requires no supervisory duties. These three grades correspond to the titles of Supervising Sanitarian, Sanitarian, and Assistant Sanitarian.

Table 1 shows classification sug-

III. BROAD EDUCATIONAL BACKGROUND (UNDERGRADUATE)

A. Institutions Offering Four Year Courses for Sanitarians

With the advent of Social Security funds for training of public health personnel, many applicants with bachelor's degrees were selected to attend courses for sanitarians. These men had majored in bacteriology, entomology, agriculture, and the biological sciences. Due to the impetus given to the training of sanitarians, several universities considered the advisability of organizing curricula majoring in sanitation, public health, bacteriology and public health, etc. At the present time at least six universities (University of California, University of Indiana, University of Massachusetts, University of Oklahoma, Rutgers University, University of Washington) have adopted such a curriculum for fulfilling the needs in this field. A recent survey indicates that many state public health officials are interested in this type of an educational program.

The uniform curriculum, which em-

TABLE 1

| Title | Univ. Educ. | P. H. Exp. | P. H. Courses |
|------------------------|----------------|---------------|---|
| Assistant Sanitarian | 2 yrs. | | |
| Sanitarian | 2 yrs. | 1 yr. | Spec. Curriculum 1 semes. |
| Supervising Sanitarian | 4 yrs. | 3 yrs. | 1 yr. grad. study in sanitary science and public health |

gested together with the required amounts of education in the basic sciences and of public health experience.

phasizes the physical, engineering, biological, and social sciences, leads to a B.S. degree for sanitarians.

* A questionnaire was sent to the responsible civil service or merit system agency in every state. The agencies were selected from a list prepared by the Council of State Governments. Forty-one states replied. The merit system listed several positions at the county and local level as well as civil service positions for the state. There is a wide variety of titles (48) as exemplified in the following table:

State Advisory Sanitarian
Chief of Division of Sanitary Inspection
Supervising Sanitarian
Senior Sanitarian
Sanitarian
Assistant Sanitarian

Supervisor of Inspectors
Senior Sanitary Inspector
Sanitary Inspector

Some sanitarians also have been graded as administrative assistants to the health officer and as deputy health officers.

B. Proposed Educational Requirements *

On the basis of the existing requirements it would seem logical to recommend the following educational requirements for Assistant Sanitarian and Sanitarian:

The minimum qualification should be two years of college work with emphasis on biological and social sciences.

The desirable qualification should be a basic educational preparation including the physical, engineering, biological, and social sciences leading to a bachelor's degree from an acceptable institution.

The program of instruction for a bachelor's degree should be formed as follows:

The first two years—cultural courses such as English, mathematics, economics, geography, anthropology, social institutions, etc., and sciences such as mathematics, elementary bacteriology, chemistry, physics, psychology, zoölogy or physiology or general biology.

The second two years—advanced general bacteriology, medical entomology, and/or parasitology, and public health courses to include elementary public health, communicable disease control, administration, health

education, principles of environmental sanitation, epidemiology, biometry, principles and practices of water supply and sewage disposal, control of production and distribution of food and milk, and laboratory procedures used in the maintenance of a sanitary environment.

C. Personal Qualities

1. Initiative
2. Tact
3. Good judgment
4. Pleasing appearance
5. Good health and good habits of personal hygiene
6. Enthusiasm for the work
7. Ability to deal with people
8. Industrious habits of working
9. Integrity

IV. GRADUATE EDUCATION

A. A small but increasing number of sanitarians with a bachelor's degree find such satisfaction in public health that they seek further academic training at the graduate level. A few accredited schools of public health will admit sanitarians with a bachelor's degree for work toward a master's degree providing they are well grounded in the basic sciences and have had suitable experience of at least three years. Some sanitarians go on to graduate degrees in bacteriology, health education, medicine, veterinary medicine, and engineering.

B. It is recommended that sanitarians wishing to devote their careers to supervisory positions in this field seek one year of graduate work in public health to supplement their undergraduate training and their work experience. Courses should be selected in conference with the faculty of the school, placing major emphasis on public health administration, epidemiology, public health statistics, or on engineering, according to the individual's needs. Obviously, such advice and courses are best obtained in accredited schools of public health. Such schools now are:

1. University of California School of Public Health

* Analysis of Present Educational Requirements

An analysis of 138 positions listed by the merit system shows an average education requirement of 2.9, or, approximately 3 years of college, plus 2.35, or approximately 2½ years' experience. Approximately 33 per cent of the total required public health training courses at a college level. Experience has been substituted for college education to a limited extent in many of the requirements, probably in order to satisfy current employment needs.

Analyzing the 138 positions mentioned above, ten may be classified as Highest Grade, 36 as Intermediate Grade, and 92 as Lowest Grade.

For the Highest Grade an average of 4 years of college and 5½ years of experience are required. Six of the ten positions demand special public health training courses.

For the Intermediate Grade, 3.8 years of college are required with 3.4 years of experience. Fifteen of the 36 positions must have public health training courses.

For the Lowest Grade, 1.9, or approximately 2 years of college are required with 1.6 years of experience. Twenty-four of the 92 are asked to have special training courses. It is interesting that this group contains 29 positions requiring college graduation against 27 requiring high school diplomas only.

Three states (California, New Jersey, New York) have legal requirements which specify educational and experience standards for the employment of sanitarians by local health units.

THE SCIENCE AND ART OF HEALTH ADMINISTRATION

THE health officer must know something about bacteriology and epidemiology and sanitation and statistics and personal hygiene; about tuberculosis and venereal disease and child health; about public health nursing and health education. On technical points, however, he can turn to expert advisers—his division chiefs in a large department or the corresponding officers of the state health department in a small one. There are two functions, however, which must always be his primary responsibility—the planning and direction of the work of his department and its interpretation to, and integration with, the other agencies and the community as a whole. After all, public health administration is *administration*.

This is why we asked a group of outstanding health officers to contribute to a symposium in this issue of the *Journal* brief statements of specific administrative problems which they have faced during the past year. The result is a highly significant cross-section of the actual tasks of the health officer. The contributions to this symposium range from broad program planning on a state-wide basis, through the machinery of amalgamating a city and a county health department, to the challenging task of obtaining funds and the effective allocation of state and federal aid to local units, the housing of the city health department, the development of broad personnel policies, and the in-service training of new employees, and, finally, to the establishment of sound and fruitful relationships with the voluntary health agencies of a county area.

These are the sort of problems presented to every health officer; and upon their solution depends the ultimate success of his work. The American Public Health Association has sought—so far, without success—to obtain funds for a comprehensive time-study of a series of representative health departments to obtain a clear picture of the functional activities of the health officer's day. A competent observer should spend a week in each department, at the administrator's elbow, recording the number of minutes spent in dealing with technical problems of various sorts, with details of routine administration, with public relations, with internal departmental diplomacy, with inter-departmental correlations. We strongly suspect that such a study would demonstrate that executive

planning and diplomacy are of far greater quantitative importance than decisions with regard to technical problems of public health science. If this should prove to be the case, the findings might suggest radical changes of emphasis in many of our schools of public health.

THE UNITED STATES PUBLIC HEALTH SERVICE

THE United States Public Health Service celebrates this month its 150th Anniversary. To join in that celebration, we must exercise a certain freedom of historical imagination; for there was—in name—no “United States Public Health Service” a century-and-a-half ago, or even half-a-century ago. A hundred years ago, the organization in question did not exercise any of the characteristic functions of a national health department. Yet we may properly honor a living and growing organ of our federal government, even if its name and its activities have altered with the passing years.

The work of the “Marine Hospital Service” began in 1798 as a function of the U. S. Treasury Department. It was initiated for the single purpose of providing care for those sailors of the Merchant Marine who were taken sick on shipboard and had to be provided with medical care in seaports where they had no legal residence. This service was paid for (in part) by deductions from the wages of the sailors; so that the United States was a pioneer in the field of national compulsory health insurance—a field which is still a fairly live subject of political discussion in 1948. As early as 1800, the first Marine Hospital was established to provide such care; but the service was only formally “organized” in 1870 under a medical director with the munificent salary of \$2,000, plus travel expenses.

Not till 1878 was the service made responsible for seaport quarantine, thus becoming in actual fact a “public health service”—a logical step, in view of the fact that it had, by this time, marine hospitals at the principal ports; and functions of interstate quarantine were assumed only in 1893. The law of 1878 embodied another most important new departure, since it gave authority for investigating the origin and causes of epidemic diseases, especially yellow fever and cholera, and the best methods of preventing their introduction and spread. The first bacteriological laboratory was established at New York in 1887, and moved to Washington in 1891. This was the basis of the Hygienic Laboratory.

After more than a hundred years of gestation, the gradual development of functional activities led in 1902 to a change in name from the “Marine Hospital Service” to the “Public Health and Marine Hospital Service” which in 1912 became simply the “U. S. Public Health Service.”

The old functions of operating marine hospitals, of enforcing maritime and interstate quarantine, of controlling the health supervision of immigrants have, of course, been continued. In the present century, however, they have been overshadowed by two activities of far greater significance—the prosecution of fundamental research and the promotion and stimulation of state and local health services.

As early as 1908 the Hygienic Laboratory published a classic report on milk supply and the public health. In 1901, and again in 1912, its research activities were broadened and deepened. Twenty-five years ago the writer of this editorial was a member of a small group, under the chairmanship of Dr. W. H. Welch, to study the research work of the Service. We spent several days in hearing

reports of studies ranging from immediate epidemiological problems to the chemistry of the rare sugars; and at the close of our conferences, Dr. Welch said to Secretary Mellon that there was no research institute in the world which was making such distinguished contributions to basic research in public health. That preëminence has been maintained in the study of tularemia, of murine typhus, of Rocky Mountain spotted fever, of pellagra, and scores of other vital areas of investigation. The conversion of the Hygienic Laboratory into the National Institute of Health in 1937 recognized notable successes in the past and paved the way for even greater progress in the future.

The development of a federal policy of grants-in-aid for stimulating state and local health services initiated another far-reaching field of influence for the U. S. Public Health Service—a field which has proved most fruitful during the last quarter century. The Service has been most fortunate in its inspired leadership during this period. Hugh S. Cumming, Surgeon General from 1920 to 1936, laid the foundation for a new spirit in the organization by bringing to the top a group of outstanding young men who have since been in the forefront of advance. Thomas Parran, Surgeon General from 1936 to 1948 made an extraordinary record. The initiation of a comprehensive research project on the control of cancer (1937), of nation-wide programs of venereal disease control (1938), of tuberculosis control (1944), of mental hygiene (1946), and the development of a program for hospitals and health centers throughout the nation (1947) have revolutionized public health work in every state and local area in this nation. In 1900 the budget of the Marine Hospital Service was \$1,371,000; in 1947–1948, that of the U. S. Public Health Service (including grants-in-aid) was \$117,848,000. The Service today has some 16,000 employees. Its future progress is assured by the appointment as our new Surgeon General of Leonard A. Scheele, whom Dr. Parran has described as “one of the outstanding figures in public health in the United States, possessing both the professional and personal qualifications to be a great Surgeon General.”

We still sometimes hear slighting remarks about “state medicine.” Well, the history of the U. S. Public Health Service is a chapter in the story of State Medicine; for State Medicine is health care provided by physicians and other health workers employed by the state. The tale is an inspiring one.

It shows, on the one hand, that our country has recognized that the protection of public health is a vital and essential responsibility of government—that, as Jefferson said, and Lincoln quoted with approval—“the legitimate object of government is to do for a community of people whatever they need to have done but cannot do at all, or cannot do so well, for themselves in their separate and individual capacities.”

A second moral of the tale is that physicians and other public health personnel do not lose their free initiative or their sense of responsibility because they are on a salary and not paid for each individual service rendered. These are not men and women who work primarily for financial reward but for the joy of service. Their record of achievement fully disproves the assumption that medical care under health department auspices tends to suffer deterioration in the quality of the service rendered.

The physicians, the dentists, the nurses, the engineers, the laboratory experts, the statisticians, the health educators, who wear the insignia of the United States Public Health Service have, for a century-and-a-half held high the standard of Aesculapius. They have brought honor to the Service whose uniform they wear;

and to the various professional groups which are united under the banner of Public Health in a common service to mankind.

A TALE OF TWO TERRITORIES

WHEN we think of the United States, we often forget that the Stars and Stripes flies north of latitude 70° and west of longitude 168°; south of latitude 20° and east of longitude 66°. Our two extreme territorial areas, Alaska and Puerto Rico, have recently been in the limelight from a public health standpoint in a way which reminds us vividly of our responsibilities for these distant areas.

A year ago, the Secretary of the Interior asked the American Medical Association to organize medical missions to visit these two regions with regard to "what measures might be taken to improve the medical care of the indigent." The reports of both these missions have now been published. They have not limited themselves to the "medical care of the indigent." The distinguished clinicians concerned have been largely preoccupied—and quite rightly—with the urgent need for basic public health work and with the fundamental economic problems of these areas, so that their observations are of great interest to the members of the American Public Health Association.

The Alaska report¹ points out that this Territory includes an area of 568,000 square miles (twice the size of Texas and one-fifth of the area of the United States proper), with a population of about 100,000 persons. Approximately one-third of these are natives (Eskimo and Indian). The Alcan Highway and the Army and Navy personnel assigned to this highly strategic area have brought in a high proportion of temporary residents who do not pay taxes in the Territory and greatly complicate its problems. The northwestern parts of the area are in the region of permanent frost which makes the tasks of sanitation difficult; and even in the southeast, sanitary conditions are very poor. Most of the food required by the population must be imported.

The most serious health problem of the territory is tuberculosis. The death rate from this disease is 359 per 100,000, nine times the rate for the United States. Even among the non-native group it is double our rate (of about 40); and among the native group, fourteen times that figure. Tuberculosis accounts for one-fifth of all deaths; and 60 per cent of the fatal cases are reported only on the death certificate. There was no sanatorium in the territory prior to 1945. There are now only 250 beds, half of which were not in operation last year as a result of failure of Congressional appropriations. The Medical Mission estimates that at least 1,000 beds are needed.

Corneal opacities (of unknown etiology) are very common among the Eskimos but there is no resident ophthalmologist in the area. Venereal disease is extensive, fostered by the large floating male population and an open prostitution district in Fairbanks; and necessary drugs for treatment are lacking. Communicable diseases are prevalent, with no adequate isolation facilities. Hospitals are inadequate in number of beds, of dangerous non-fire-proof construction, and ill-equipped. There is no mental hospital in the territory; patients are sent to an institution in the State of Oregon, under a peculiarly vicious commitment law. Housing in the territory is even worse than with us in the United States (which is saying something). For this reason, and on account of high cost of living

pal hospitals (except the one at San Juan considered as "excellent") are on the whole very poor. The Mission suggests that they might with advantage be transferred to the Insular Government.

There are only about 800 physicians in Puerto Rico, less than a third of the number necessary for service by our continental standards. To meet the needs of the rural areas, the Insular Department of Health has established 65 district health units providing both medical care and public health services, and 21 additional units for preventive services only. Each of the major units is in charge of a (supposedly) full-time medical health officer; but it is believed that many of these officers actually engage in private practice. The Mission was not favorably impressed with the quality of service rendered. From the standpoint of the health administrator it might be preferable to have a considerably smaller number of independent jurisdictions under health officers so recompensed as to secure real full-time leadership. The Mission pays a deserved tribute to the School of Tropical Medicine at the University of Puerto Rico in San Juan which is operated with the coöperation of the School of Public Health of Columbia University. Dr. E. E. Irons, Chairman of the Mission, says "The School of Tropical Medicine has been, in my opinion, the greatest single factor in improving educational standards in medicine in Puerto Rico."

The results of the general public health program carried out in Puerto Rico during the past decade have been notable. In 1937 the general death rate was 20 per 1,000; in 1947, 13 per 1,000. In the year 1945, the specific death rate from typhoid fever had been reduced to 3 per 100,000; that from diphtheria to the same figure; that from dysentery to 6 per 100,000. These rates represent notable achievements. The three major challenges, not yet met, are diarrhea and enteritis (290 per 100,000), tuberculosis (202 per 100,000), and malaria (43 per 100,000). The Insular Department of Health is well organized, with Bureaus of Vital Statistics, Epidemiology, Sanitation, Tuberculosis, Malaria Control, Venereal Diseases, Maternal and Child Health, Crippled Children, Laboratories, Public Health Nursing, and Social Services. Notable progress has been made in Health Education and the island has 31 trained experts in this field, a larger number than could be found serving a similar population in most states of the Union. The Puerto Rico Public Health Association with 400 members, is one of the most active of the Affiliated Societies of the American Public Health Association; and those of us who had the privilege of attending its meetings last spring were deeply impressed with the eager and progressive spirit of the health workers of the island.

The fundamental health problem of Puerto Rico is an economic one, related to over-population. The average family income of the island is deplorably low and the cost of living somewhat above that of the Continental United States, since all food (but sugar) and most of the other necessities of life must be imported. Malnutrition is widespread and serious. It is encouraging to note that birth control has been legalized by the Supreme Court of the island and that 27 birth control clinics are in operation; but their total effect has done no more than check further pyramiding of population increase. Some emigration is taking place to the United States; but not enough to help materially. The most promising factor in the situation is an encouraging spirit of constructive planning, for the development of local industry (such as glass bottle and paper carton and cement plants now in operation); the increase of the fishery business, which has real possibilities; the furtherance of home industries (for which the

Puerto Ricans have special aptitudes); and the development of tourist trade.

The people and the Government of Puerto Rico are meeting the challenge of their unbalanced economy with courage and vision. For the present, they need, and deserve, far more substantial aid from the federal government than they have yet received. The Territory of Alaska and the Island of Puerto Rico are handicapped—in quite different ways—by conditions beyond their control. They lack the direct and effective share in their own government, on a natural level, which statehood would involve. They are, in a sense, wards of our Government; and that Government has failed to meet adequately its responsibility for their welfare.

PITTSBURGH'S MAYOR DECLARES HIMSELF

At an address on May 5 before the Nurses' Alumnae Association of Presbyterian Hospital, Pittsburgh, Mayor David L. Lawrence devoted his attention to public health in Pittsburgh. Mayor Lawrence expressed appreciation to the U. S. Public Health Service which is completing a survey of public health in Pittsburgh under the direction of Dr. E. R. Coffey, Medical Director of District No. 1, New York. The Mayor said that the city would not be abashed if some phases of the report were critical, for that is what was wanted—a fair appraisal of the virtues and failings, an analysis of successes and shortcomings.

"To our community program we will add a determination that here in Pittsburgh we will have a public health program which will equal the nation's best—which will make this city as preëminent in the health work that is done here as it is now preëminent in the economic life of the nation. I have been vastly heartened by the citizens' interest that is stirring in this field of public health. A democratic government can go ahead only as fast and as far as the people direct it to go.

"The City Council has authorized the employment of a public health engineer to direct the city's inspectional health services and a public health nursing bureau chief to develop and expand the nursing phase of the department's work. We are scouring the country now for the best people for these jobs. . . . In my fixed belief, key public health positions are not patronage of any kind, political, medical, or anything else—and never should be. The test must be qualifications. The field of public health is a specialized area, increasingly so. It requires special training, as other medical and nursing specialties require training. We are seeking people with that special interest and special ability in public health work."

DR. TURNER SUMMARIZES FOR PTA

The Health Conference of the National Congress of Parents and Teachers was held on February 17 and 18 (see

April *Journal*, p. 602). The Conference summarizer was Clair E. Turner, Dr. P.H. longtime health educator and currently assistant to the President, National Foundation for Infantile Paralysis.

A mimeographed abridged version of his summary has been received. It is worth reading for a number of reasons, not the least of which is its informal, chatty style such as the professional expert achieves too infrequently.

It is further notable for its recognition of the fact "that a good general health program lies at the basis of any special health activity."

In brief form, Dr. Turner picked up the threads of discussion so that his summary is itself a handbook of suggested aids, "most progress is probably going to be made through state and local health councils" to which he adds that the National Health Council can aid in organizing such councils.

In "extending knowledge of what constitutes a good local health program," he suggests the *Evaluation Schedules* for Use in the Study and Appraisal of Community Health Programs by the A.P.H.A., and the *Appraisal Form* for Evaluating School Health Services by the American School Health Association and the Michigan School Health Association.

If you can get this document from the National Congress of Parents and Teachers (600 S. Michigan Boulevard, Chicago 5), it will give you much factual information as well as serve as a model in case you find yourself with the job of summarizing a conference.

HEALTH IN BROOKLINE TOWN

The town of Brookline, Mass. (really a city of 50,000), calls its spring quarterly *Health Bulletin*, "Health in Our

Town" which is the annual report of its health department, Alfred L. Frechette, M.D., Commissioner. It has attractive photography and unique charts picturing some of the town's vital statistics. Even its organization chart is pictographed.

HEALTH ON THE RADIO IN OKLAHOMA

The Oklahoma State Health Department has prepared a radio series "Spotlight on Health" intended for grades 5-8. The series is a weekly program over the University of Oklahoma Radio Station. The pamphlet *Spotlight on Radio* includes a teachers' manual which gives many more suggestions for health teaching than can be done in a 15 minute radio period.

Among the special features of this manual are that it was written largely by rural school teachers, and that school children helped to select titles.

NURSING IN PICTURES

The Department of Hospitals of the City of New York has made its own contribution to the recruitment of nurses program in an attractive booklet entitled "Nursing—A Growing Profession." Detailed photographs of all phases of the nurse's training illustrate the pamphlet which includes also the details of courses, equipment, and costs in each of six nursing schools in municipal hospitals. There is a section, with pictures, on opportunities for the graduates, among which is an "excellent background for marriage and family life."

The photography and printing are excellent. Published by the Department of Hospitals, 125 Worth St., New York 13, N. Y.

ABOUT FEDERAL RESEARCH GRANTS

For the benefit of deans of medical schools, recipients of research grants from the U. S. Public Health Service, and others, the Division of Research Grants and Fellowships of the Service

has abstracted the laws, rules and regulations relating to the operation of the research grant program. A 12 page mimeographed document is available from the National Institute of Health, Washington 14, (Bethesda Station) D. C.

At the same time the Division of Public Health Methods in *Supplement No. 205* to the *Public Health Reports*, January, 1948, has listed all research grants made between January 1, 1946, and August 31, 1947. In that period grants of more than 10 million dollars have been made to 629 scientists for 699 projects in 193 institutions.

AS SIMPLE AS $2 + 2 = 4$

Using this simple arithmetic as a symbol, the Indiana Health Advisory Council (1098 W. Michigan St., Indianapolis 7) has recently issued an attractive booklet whose message is "The Law + Community Action = A Healthy Community." Using the question and answer method and illustrated with marginal drawings, it tells what a county health department is and how to get one, also a city-county or multiple county department. The names of the Indiana Health Advisory Council from O. O. Alexander, M.D., of the State Medical Association to A. P. Zetterberg of Rotary International, and 43 in between representing the professions, business, labor, the church, universities, and all the forces directly or indirectly interested in public health in the state are the clue to the present state-wide interest in getting more adequate health services in Indiana.

A BIRD'S-EYE VIEW

Health for a Million is a folder prepared by the Cleveland Division of Health for general public distribution. In bird's-eye paragraphs, each illustrated with a suitable drawing, it tells how the division operates and what it is doing to protect and improve the health

of Clevelanders, now numbering nearly a million. A brief history of the department is included, a look into its future problems, and the addresses of the 7 health centers and 5 branch child welfare stations. Altogether an attractive, useful aid in keeping in touch with your public.

FINDING CANCER IN THE BACK COUNTRY

Cancer detection clinics are scarce in the rural and mountain areas of Kentucky. But the Junior League of Kentucky has found what the *Junior League Magazine* (May, 1948) calls "the first unit of its kind in the world" to take the place of such clinics.

It has presented the Kentucky Chapter of the American Cancer Society with a Cancermobile armed with complete x-ray equipment, examining room, laboratory table for examining biopsy specimens as well as fluorescent lighting, electric heater, etc.

The Cancermobile visits counties on invitation of the County Medical Society and accepts patients only on referral from private physicians. But the visit is preceded with advance radio and press publicity and with visits of the Cancer Society's field director who speaks on cancer control in schools, churches, men's and women's groups, etc. The aim is not only to publicize the coming Cancermobile but to get cancer education to the community.

The Cancermobile is staffed with a physician, secretary, registered nurse, driver of the unit who also develops x-ray pictures, the Cancer Society's field director, and one or two members of the Louisville Junior League as volunteer general helpers.

CANCER STUDY CONTEST IN HIGH SCHOOLS

The New York City Cancer Committee this year has sponsored the sixth annual High School Cancer Study Contest open to students in public, private, and

parochial schools. These contests are arranged to encourage students, and through them their families, to acquire up-to-date knowledge on cancer and related diseases. Prizes are given to the schools for group exhibits as well as posters prepared by groups or individuals.

More than 400 posters and a good number of exhibits and models prepared for this contest were shown at the Museum of Natural History in April and May. Many of the exhibits involved a considerable amount of study, teamwork, imagination, and technical ability. Artistic talent was ably expressed in many excellent posters, making it difficult for the judges to make their decisions. The scientific exhibits included such material as cancerous animals and plants, tools for cancer therapy, methods for cancer research, and material aimed at cancer education.

Credit is due the New York City Cancer Committee for realizing that accurate knowledge is best acquired by active participation in group projects during the formative years; to the science and art teachers whose splendid guidance is evident throughout the exhibit; and to the students who were able to direct scientific information into creative channels.

ECPD—A CHALLENGE

The above is the title of a booklet prepared by the Engineers' Council for Professional Development which is described as, "An Audit of Accomplishments 1932-1947 and a Rededication of Plans for Future Action." The brief account, giving the history of ECPD, quotes from the 1932 Charter in describing the purpose of the organization as "a conference body organized to enhance the professional status of the engineer through the coöperative support of those national organizations directly representing the professional, technical, educational, and legislative phases of an engineer's life."

Listed among the accomplishments of the first 15 years of activity is the inspection and evaluation of 678 engineering curricula of which 580 were accredited. Two other noteworthy accomplishments described are the preparation, after extensive trial, of entrance examinations "Pre-Engineering Inventory" and a second series of examinations entitled, "Engineering Achievement Tests."

(Editor's note—Abel Wolman, Dr. Eng., representing both organizations, is chairman of an APHA-ECPD committee currently exploring the field of graduate work for engineers entering or returning to public health.)

A SURVEY OF MEN NURSES

It is understandable that the New York State Nurses Association should be the first to conduct a survey of men nurses (*Men Nurses, Education and Employment*, New York State, April, 1948), for 22 of the 43 schools of nursing in the United States which admit men are within the state. Over 600 men have graduated from the New York schools in the past ten years.

Areas of service include boys' schools, blood banks, health departments, and the Department of Correction, in addition to more familiar activities such as employment in industry, mental hospitals, general hospitals, and private duty nursing. The survey points out that the greatest drawback to basic education of men nurses is the problem of housing: the greatest drawback to general employment of graduates is due to the need in many agencies to make their employment selective.

The survey concludes that more male nurses are needed and that there are strong arguments for recruiting men into the nursing profession.

A "Highbrow" Magazine Discovers
Public Health
The *New Republic* recently began a

series of special reports on "1948: The Issues." The first in this series in the May 3 number, was a health "package" including an editorial and two articles on "The State of the Nation's Health" and "Playing Politics with the Health Issue" by Carl Malmberg, M.D., and Helen Fuller, respectively. The articles are interestingly illustrated with pictorial charts in color.

WORTH ACQUIRING

Some Special Problems of Children, Aged 2 to 5 Years, is the general title of a series of pamphlets, the first eight of which are now available. Planned and written by Nina Ridenour in collaboration with Isabel Johnson, they have been published and are being distributed by the New York Committee on Mental Hygiene of the State Charities Aid Association (105 East 22nd St., New York 10).

Their purpose is described "to bring to parents and teachers a point of view which will make their relations with children smoother and more constructive and will give children greater opportunities for happiness." The eight titles are: *When a Child Hurts Other Children*, *When a Child Is Destructive*, *When a Child Uses Bad Language*, *When a Child Won't Share*, *When a Child Still Sucks His Thumb*, *When a Child Still Wets*, *When a Child Masturbates*, *When a Child Has Fears*. Single copies 10 cents, packet of 8, 75 cents.

Money Saving Main Dishes has 150 tested recipes especially prepared by the Bureau of Human Nutrition and Home Economics of the U. S. Department of Agriculture. The recipes are planned to use cheaper forms of protein and yet feed the family adequately. Free by addressing Food Conservation, Washington 25, D. C.

Industrial Health: A Guide for Medical and Nursing Personnel is published

by the Industrial Health Committee of the Wisconsin State Medical Society in coöperation with the Industrial Hygiene Unit of the State Board of Health. This brings up-to-date a pamphlet first published by the Wisconsin Society in 1932, which "has done much to improve the quality of services in Wisconsin industries." Presumably available from Wisconsin State Medical Society, Madison, Wis.

How to Build a Safer Home has been prepared by the *Good Housekeeping* Building Forum with the purpose of

pointing out how to guard against the danger spots in the home. It is illustrated liberally with drawings, often showing both the right and the wrong way of doing things. Available from *Good Housekeeping* Bulletin Service, 57th St. & 8th Ave., New York, 35¢.

Butch Learned the Hard Way, with suitably amusing drawings, has all the basic rules of shop safety in compact form and colloquial language. Prepared by and available from the Bureau of Labor Standards, U. S. Department of Labor, Washington 25, D. C.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unpublished reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

Physical Fitness Appraisal and Guidance—By Thomas Kirk Cureton, Jr., and Frederick W. Kasch, assisted by John Brown and W. G. Moss. St. Louis: Mosby, 1947. 566 pp. Illus. Price, \$6.00.

The purpose of this reference as stated in the preface is to provide an "interpretative book on physical fitness" for physicians and nurses as well as physical educators. Many of the data presented are based on a project designed to promote physical education for first year students in the Colleges of Medicine, Dentistry, and Pharmacy at the University of Illinois.

Appraisal of physical fitness is approached from the point of view of determining physique, organic efficiency, and motor fitness. This is the same emphasis described in a previous publication by Cureton.* Mention is made of health examination tests and other approaches to fitness but the emphasis on the three approaches selected is justified on the basis of practicality and previous research in these areas.

Considerable attention is given to a review of the literature dealing with methods of appraising body types, weight, cardiovascular and respiratory fitness, strength and motor performance. In fact the strength of the book lies in the extensive bibliography it presents, since many basic studies are cited.

The project conducted with 110 first year medical students to stimulate their interest in physical education and increase their understanding of physical

fitness constitutes the "original" material for this book. Tests used with this group included anthropometrical measurements, somatotype ratings, the Schneider and other tests of cardiovascular efficiency, vital capacity and other means of respiratory fitness, and a battery of motor performance tests including the one mile run. The discussion of these tests is distributed throughout the reference, making it difficult to discover the total results and conclusions of this study.

Suggestions for the health and fitness guidance of the individual based on the results of these various tests also appear in a number of chapters. For the most part these suggestions stress the importance of exercise, especially "endurance exercises." Generalizations, based presumably on the data presented, to support this recurring suggestion may be questioned in a number of instances; for example, mental hygiene guidance for body types (p. 129), dieting (p. 155); exercise to improve cardiovascular condition (p. 189), and a low basal metabolism (p. 304).

From the quality of the writing one gains the impression that the literature cited and the data presented have not always been interpreted too objectively and that the authors' apparent conviction of the importance of endurance exercise as a means of attaining optimal physical fitness has influenced particularly the suggestions given on guidance. Such expression will lend strength to the criticisms, certain to be made, that the book presents a biased viewpoint and overlooks or passes lightly over interpretations that do not support the

* Cureton, Thomas Kirk. *Physical Fitness Workbook*. (2nd ed.) St. Louis: Mosby, 1947. Reviewed in *A.J.P.H.*, 37:1193 (Sept.), 1947.

thesis that endurance exercise is the most important factor in physical fitness. Physiologists, physicians, public health workers, as well as educators and others who read this book should do so critically to gain the greatest value.

MABEL E. RUGEN

A Textbook of Bacteriology—By *R.W. Fairbrother, M.D., D.Sc., F.R.C.P.* (6th ed.). New York: Grune & Stratton, 1948. 480 pp. Price, \$6.00.

The volume under review is a 1948 United States published reprint of the fifth edition of Dr. Fairbrother's concept of the medical aspects of bacteriology. This English author restricts his attention to "bacteria as agents of disease in man, and the application of bacteriological methods in the prevention, diagnosis, and treatment of disease," incorporating newer bacteriological knowledge into a well organized and logical presentation for the medical student.

The first section concisely covers the essentials of general bacteriology in progressive steps from the initial historical survey through the elementary background of morphology, biology, growth and destruction of bacteria; types of infection and immunity; significance of antigens, antibodies and their reactions; a chapter on chemotherapy even recognizing its limitations. Throughout the textbook the nomenclature is British for, although reference is made to the 1920 classification of the American Society of Bacteriologists, the 1947 contribution of the International Society for Microbiology has necessarily not been incorporated. The chapter on bacteriology and medicine might well be considered an excellent fundamental basis for thoughtful and careful coöperation between physician and laboratory with the ultimate objective of successful bacteriological or serological diagnoses.

The second section devoted to sys-

tematic bacteriology, comprehensively treats each pathogenic microorganism, its essential characteristics plus its medical aspects, laboratory diagnosis and types of therapy. Tables of reactions are graphic. Characteristic named phenomena of diagnostic significance and specialized tests are appropriately included, and desirable epidemiology is stressed. Human virus diseases are well classified and discussed, emphasizing the success of complement-fixation studies and neutralization tests.

The brief third section on general technique is recognized universal practice, with a rarely noted deviation from United States standard methods.

Since information in this textbook is authenticated, the material comprehensive, and the presentation interesting, it may be recommended as a constructive study of principles and development of medical bacteriology.

CATHARINE ATWOOD

Public Health—A Career with a Future—*American Public Health Association.* (rev. ed.). New York: American Public Health Association, 1948. 19 pp. Price, \$15.

Public health needs more trained workers. How do you recruit for this field? How do you capture the interest of the professional graduate, the college freshman, or even the junior in high school? One approach is obviously through the pamphlet which describes the field and the opportunities in a straightforward, accurate, and yet alluring manner.

The above named pamphlet was prepared by the A.P.H.A. some two years ago. The revised form now issued is 10 pages shorter. It tells the story with vocational and public service appeal. The different types of positions in public health are listed, but the more detailed descriptions of the nature of the work in special fields, the educational qualifications, and the salary

series of investigations designed to test the "effect of added thiamin in the average diet on learning, the ability to memorize, on forgetting, on certain sensory and motor activities, on health, and on the growth of mind and body in normal children."

The subjects were 120 children, living in an orphanage. Sixty of the children served as experimental subjects and 60 as control subjects. The children in the experimental group were given daily a 2 milligram tablet of thiamin, while those in the control group were given daily an indistinguishable placebo. The study began in the spring of 1941 and terminated in the early fall of 1944. During the last year of the study, one-half of the groups were reversed, thus excluding the possibility that the children originally chosen for the thiamin supplementation were accidentally somewhat superior genetically or otherwise.

The tests given were those that measured gains in the performance of mental tasks.

The institutional diet was of necessity a low cost one. It was high in cereals and low in meat, but the liberal use of milk, butter, and cheese provided meals that were adequate in all respects except thiamin, the average intake of which was estimated to be 1.0 milligram per person per day. Had the cereals been of the enriched type even this low cost high cereal diet would have been adequate in all respects. This is the type of investigation which can illustrate the value of cereal and flour enrichment.

During the first 6 weeks of experimentation the thiamin-fed group made superior gains in all 18 test tasks. In the ensuing period of 1 year the thiamin-fed group again surpassed the control. In the final year, the reversal period, the group receiving thiamin for the entire period continued to demonstrate superior gains. The reversed pairs demonstrated reversals of superior gain

in one-half of the activities, but failed to show adverse effects of thiamin withdrawal.

The author conservatively concludes that: "It is clear from the studies herein reported that the results of thiamin supplementation are not sufficiently great to be observable over short periods of time in all measures of performance. The cumulative effects of a superior dietary throughout life may, nevertheless, spell the difference between alert, successful living and a marginal effectiveness."

ALICE H. SMITH

How Life Is Handed On—By Cyril Bibby. New York: Emerson Books, 1947. 159 pp. Price, \$2.00.

Although "telling about the birds and bees" has become a stock ingredient of much hammy humor by radio comedians, plant and animal reproduction continues a good basis for sex education. Bibby uses it advantageously in this new volume. In addition to being a sound scientist he is a good story teller—one who knows how to make life and growth not merely tolerable but interesting.

His practical application of science is intended for children and younger adolescents. Hence his appeal often is directed to their self interests through which broader, more altruistic connotations readily can be implied. Here is an example. After asking his youthful reader what would happen if living things did not hand life on from generation to generation, he answers by telling them, "Hens would not have chicks, so there would be no eggs for your breakfast. Cows would not have calves, so there would be no milk for your mid-morning drink. Sheep would not have lambs, so there would be no roast lamb for your dinner. But that would not worry you, for if humans did not have babies there would be no *you* to worry!"

In his dealing with human reproduc-

live processes, the author presents major factors without going into boresome obstetrical minutiae. His illustrations and glossary add value, and the large type makes for easy reading. Adding to its usefulness as a medium for sex education, Bibby weaves tradition, social standards, and personal character guidance nicely into the textual pattern. Conscientious parents and educators will find in this book another valuable base for building essential knowledge and philosophy into young lives.

RAY H. EVERETT

Advances in Military Medicine. Vols. I and II—*Edited by E. C. Andrus, D. W. Bronk, G. A. Carden, Jr., M. C. Winternitz, J. S. Lockwood, J. T. Wearn, and C. S. Keefer.* Boston: Little, Brown, 1948. 990 pp. Price, \$12.50.

These volumes constitute the official record of progress achieved in many fields by American investigators working under the sponsorship of the Committee on Medical Research of the Office of Scientific Research and Development.

Subject headings indicate the broad scope of the report: Medicine, Surgery, Aviation Medicine, Physiology, Chemical Warfare Agents, Anti-Pest Agents, Adrenocortical Steroids, Malaria, Penicillin, and Sensory Devices.

Joseph Earle Moore relates how it was learned that soap-and-water washing was of no value in prophylaxis of chancroid in volunteers deliberately inoculated, but that sulfonamides applied locally were effective. Eventually the Army adopted a single-tube prophylactic against venereal disease containing 15 per cent sulfathiazole and 30 per cent calomel in a vanishing cream base.

Those concerned with blood banks will be interested in Cohn's chapter on plasma fractionation, Janeway and Oncley's on blood substitutes, and Guest's on methods of preservation of whole blood.

Gordon M. Fair reviews the studies on water disinfection and gives data on survival times of certain pathogens under varying conditions of pH. Iodine was found preferable to chlorine for individual canteen water treatment on the bases of palatability, rapidity of disinfection, and ease of application. Tablets of a newly synthesized compound, triglycerine hydroperiodide, were developed for use of individuals in the field.

The story of the experiments with DDT and other new insecticides, with the rodenticides, sodium fluoracetate (1080) and alpha-naphthylthiourea (ANTU), is still amazing. It seems almost incredible to read that over 7,000 repellents and mixtures were tested at the Orlando, Fla., laboratories of the U. S. Department of Agriculture. Liquid repellents were compounded for skin application that were 100 per cent effective against *Aedes aegypti* for over 3 hours.

Carden, Elderfield, and Taliaferro tell of the testing of more than 14,000 compounds against one and often two or three avian malarial parasites in different hosts. Shannon reports on the many coöperative studies in testing the most promising of these compounds on volunteers, as a result of which at least one appears highly effective in suppressing malaria and another appears to have definite curative power against *vivax* infection.

Although most of the material contained in these volumes has been published previously in scientific journals, epidemiologists and sanitarians will find these concise summaries more convenient for reference purposes.

FRANKLIN M. FOOTE

IES Lighting Handbook—*Compiled under the auspices of the Illuminating Engineering Society. (1st. ed.).* New York: Illuminating Engineering Society, 1947. 856 pp. Price, \$7.50.

This first edition of the *IES Lighting Handbook* is of great value to the engineer who is interested in the field of illumination. There has been a need for a book like this for many years. The handbook condenses the accumulated knowledge of the past 40 years of lighting progress. It is evaluated and interpreted for convenient use of the lighting engineer. The book is divided into the Reference Division, Application Division, and Manufacturers' Data Index.

The Reference Division has 9 sections. Each of these sections briefly describes and gives pertinent data on the physics of light production, light and vision, standards, nomenclature abbreviations, color, measurement of light, light sources, light control, light calculations, and daylighting.

The Application Division has 5 sections. Each of these gives practical applications on such subjects as interior lighting, exterior lighting, sports lighting, transportation lighting, photographic, reproduction, projection and television lighting, miniature lamp applications, and miscellaneous application of radiant energy.

The illumination intensity standards as set forth in this handbook are, of course, the standards as approved by the Illuminating Engineering Society. These lighting standards at the present time are controversial. Authorities such as Dr. M. A. Tinker of the University of Minnesota have expressed concern over the increase of light intensities on the working plane as set forth by the Illuminating Engineering Society. It is understood by the reviewer that these differences of opinion are now being reviewed by a joint committee representing the American Public Health Association and the Illuminating Engineering Society.

GEORGE D. CLAYTON

Man, Weather, Sun — By William F. Petersen, M.D. Springfield, Ill.:

Charles C. Thomas, 1948. 462 pp. Price, \$10.00.

The first section of this book is devoted to a minute description of a large number of clinical observations performed on a set of young adult male triplets. In the second section the author states that "the evidence has been presented that the organic rhythm observed in the triplet group during June and July of the year 1940 could be observed in the general population." A number of graphs are used as evidence, including one (Fig. 154, p. 190), showing the sex ratio of persons dying in relation to the specific gravity of the urine of one of the triplets. In all, the book contains 294 charts and diagrams, many of them insufficiently labelled to permit interpretation. These charts, incidentally, are similar to those presented by Dr. Petersen in other of his writings.

The language used in this book is quite foreign to most students of medicine or public health, but seems to have much in common with that used by astrologers. As an example, the following passage is quoted (p. 110): "This brain was congenitally predisposed to early disturbance and the vascular state of the time merely pushed the amplitude of clinical reflection back and forth."

LEONARD J. GOLDWATER

Private Enterprise or Government in Medicine — By Louis Hopewell Bauer, M.D. Springfield, Ill.: Charles C. Thomas, 1948. 201 pp. Price, \$5.00.

The excellence of this volume consists chiefly in the convenience of access to the record of official actions, plans and programs of the American Medical Association over the decades in matters of public or social concern with medical care, and methods of paying for it.

The eleven chapters are brief, documented more by quotation than through bibliography, and carry at the

law, evidence, judicial procedure, legislative drafting, municipal corporations, and torts are all involved. Law publishers have heretofore had little occasion to promote such an organization of material, there having been no corresponding specialization in law practice, and for similar reasons the law schools have not attempted it. So far as this reviewer is aware, Dr. Tobey's is the sole up-to-date treatise on the subject, and he has done a thorough and comprehensive job. Programs and activities under the head of public health are, of course, undergoing rapid expansion. In the future such a book as this will probably be enlarged in scope to include more of the legal aspects of the administration and regulation of hospitals, clinics, and welfare institutions; of institutions and programs in the mental hygiene field; and of programs for extending the availability of ordinary medical care. Short of this, however, the author covers his field.

The book includes a short bibliography, index of cases, and an adequate topical index. The law reviews, unfortunately, are unrepresented. A selective bibliography of the comments and case notes dealing with public health issues which have appeared in these reviews—now quite numerous and in many instances of excellent quality—would have been useful. All primary sources, however, appear to have been fully canvassed. Health officers and students of public health, city and town attorneys, and all others professionally concerned with administration in this field will find the new edition of this standard work extensively useful.

GEORGE H. DESSON

The Mind in Action—By Eric Berne, M.D. New York: Simon and Schuster, 1947. 320 pp. Price, \$3.00.

The sub-title of this volume indicates that it is a layman's guide to psychiatry. The author in the first three

chapters of the book gives a background of the physical structure of the individual to indicate what he has to work with. Then follows a discussion of what human beings are trying to do and a chapter on the emotional growth of the individual. After a discussion of dreams and the unconscious, the author in the second part of his book describes the neuroses and psychoses, alcoholism, drug addiction, and certain types of behavior disorders. He follows this with a description of psychiatric treatment and of psychoanalytic treatment of mental disorders. There are two appendices, one which describes intuition and extra-sensory perception and the other describes man as a political animal.

The book is written within the frame of reference of orthodox Freudian theory. The author has also been influenced by his reading in the field of semantics with particular reference to the writings of Korzyboski and Hayakawa. At the end of each chapter are what are called footnotes for philosophers; "philosophers" being defined as those people who think about what they read. These footnotes indicate some of the divergent points of view with regard to the subject matter of the particular chapter and the references where these divergent points of view may be found in more detail. There are also a few bibliographical references in these footnotes which are in line with the point of view taken by the author in a particular chapter. These bibliographical suggestions have been exceptionally well chosen for their pertinent relevancy to the material in the previous chapter. They make no pretense of being exhaustive but are highly selective.

The author writes in extremely simple language with a minimum of technical terms. His style is witty and lay or professional readers may find considerable enjoyment in the humorous way in which material is presented.

mands on nurses is lost by the third page. As all of the material is timely, useful, and rich in content, it is regrettable that it should be offered in such jumbled order. The solution, of

course, is to read every word of the book as this reviewer has done. If you do not, you will miss valuable suggestions which are not in their logical places.

DOROTHY DEMING

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- ABOUT THE KINSEY REPORT.** Observations by 11 Experts on "Sexual Behavior in the Human Male." Edited by Donald Porter Geddes and Enid Curie. New York: New American Library, 1948. 166 pp. Price, \$25.
- AMERICAN BUILDING.** The Forces That Shape It. J. M. Fitch. Boston: Houghton Mifflin, 1948. 328 pp. Price, \$5.00.
- AMERICAN YEAR BOOK 1947.** The. William M. Schuyler, Editor. New York: Thomas Nelson, 1948. 1125 pp. Price, \$15.00.
- APPROVED TECHNICAL INSTITUTES.** J. S. Noffsinger, Ph.D. Washington: National Council of Technical Schools, 1948. 48 pp. Price, \$.25.
- CANCER—A HANDBOOK FOR DENTISTS.** Prepared by the Tumor Committee of the Connecticut State Dental Society. Hartford: Connecticut State Department of Health, 1948. 52 pp.
- CATALOGUE OF CERTIFIED PROFESSIONAL MOTION PICTURE FILMS.** Presented as a Service of Academy-International of Medicine. Topeka, Kans.: Department of Audio-Visual Aids, 1948. 110 pp.
- CAUSES OF BLINDNESS.** Among Recipients of Aid to the Blind. Ralph G. Hurlin, Sadie Saffian, and Carl E. Rice, M.D. Washington: Supt. of Documents, 1947. 131 pp. Price \$.40.
- CITIZEN PARTICIPATION IN GOVERNMENT.** Helen E. Martz, Ph.D. Washington: Public Affairs Press, 1948. 63 pp. Price, \$1.00.
- DAIRY BACTERIOLOGY.** Bernard W. Hammer, Ph.D. (3rd ed.). New York: Wiley, 1948. 593 pp. Price, \$6.00.
- DEVELOPMENTAL PHYSICAL EDUCATION.** James S. Nicoll and May Belle Long. Yonkers-on-Hudson, N. Y.: World Book Company, 1947. 232 pp. Price, \$2.44.
- ESSENTIALS OF FEVERS.** Gerald E. Breen (2nd ed.) Baltimore: Williams & Wilkins, 1948. 351 pp. Price, \$4.50.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Evaluating Epidemiologic Procedures—Venereal disease case finding is tried and found not-wanting in Toronto. Having himself given in this *Journal*—just twenty years ago—a halting account of New Jersey's first free-hand attempts to apply epidemiologic technics to the venereal infections, it is cheering to this ancient annotator to read each new account of another Cortez, "silent, upon a peak in Darien" discovering, too, that the Pacific still is there.

BROWN, W. G., and NICHOLS, W. B. Epidemiologic Procedures as a Case-Finding Mechanism in Syphilis Control. *Canad. Pub. Health J.* 39, 4:123 (Apr.), 1948.

Aid vs. Gravy—Factors used in allocation formulas for grants-in-aid should be measurable and be based on data collectable by official agencies. Flexible patterns for such aid are now being formulated, say these writers.

CHAPMAN, A. L., and GREVE, C. State-Local Grant-in-aid Formulas. *Pub. Health Rep.* 63, 21:673 (May 21), 1948.

"First the Infant, Muling . . ."—Is this something you, too, never thought much about? "There has been little attempt to measure the extent of illness among infants." So begins this study, which reveals the causes of illness (and deaths) under 1 month, 1-2, 3-5, 6-8, and 9-11 months.

COLLINS, S. D. Illness among Infants, with Comparative Mortality Data. *Pub. Health Rep.* 63, 20:637, (May 14), 1948.

"99.99+ Per cent Successful"—This breakdown of 327 outbreaks of water-borne disease involving 111,320 cases (from 1938 through 1945) will prove an excellent antidote for your complacency about our peerless sanitary safeguards.

ELIASSEN, R. AND CUMMINGS, R. H. Analysis of Water-borne Outbreaks, 1938-45. *J. Am. W. W. A.*, 40 5:509 (May), 1948.

"Maturity and Solidity" are Added—This is an eloquent plea for 1,200 local health administrative units instead of 18,000 "boards of health." You know the program: this is your opportunity to view it when presented by a master of the art of influencing men. You'll be repaid with a mine of quotations.

EMERSON, H. Whither the Pegasus of Public Health? *New England J. Med.* 238, 20: 679 (May 13), 1948.

Big Job To Be Done—Reviewing our present knowledge of environmental factors in mental health (and lack thereof) the writers discuss the vast areas in which research is needed to improve our preventive and therapeutic armamentarium.

FELIX, R. H., AND BOWERS, R. V. Mental Hygiene and Socio-Environmental Factors. *Milbank Mem. Fund Quart.* 26, 2:125 (Apr.), 1948.

Beauty Note—Lady sanitarians will be relieved to learn that ammonium thioglycolate, the chemical used in the cold-waving process, is very seldom irritating to the skin of the person being beautified, though it is often tough on the hands of the beautician. Now that home permanents are making every home a beauty parlor, the problem seems to become more complicated; doesn't it? Amateur beauticians might use rubber gloves.

GOLDMAN, L., et al. Permanent Wave Process. *J.A.M.A.* 137, 4:354 (May 22), 1948.

A Little about a Lot—Reviewing recent advances in the control of the

common communicable diseases, this article moves on to cover new problems like rickettsialpox and old ones like rheumatic fever.

INGRAHAM, H. S. Recent Advances in Communicable Disease Control. New York State J. Med. 48, 10:1135 (May 15), 1948.

Just To Stir Things Up—I believe this subject is public health. A committee of New York doctors has proposed a workable bill to make voluntary euthanasia crime-proof and lawful. "As a subject for arm-chair debate, it rivals communism in its ability to evoke bitter words and hot tempers," says the writer.

JAMES, S. Euthanasia—Right or Wrong? Survey Graphic 37, 5:241 (May), 1948.

Old Enemy Raises Ugly Head—Caused chiefly by a minimus strain of *C. diphtheriae*, a diphtheria outbreak of 117 cases—with 11 deaths—was studied. Of the minimus cases, 59 per cent had had previous immunization. In a companion paper is a discussion of certain laboratory difficulties which may in the past have led to misinterpretation.

JENKINS, A. A. Diphtheria Epidemic in Utah in 1947 (and) GALBRAITH, T. W., et al. Appearance of "Minimus" Type Diphtheria in Utah. Pub. Health Rep. 63, 18:573 (Apr 30), 1948.

Jeremiad—It is an interesting commentary on our social organization, says this writer, that two antithetical forces like war and humanitarian institutions should protect the unfit at the expense of the fit. Yet we stage a war every twenty-five years and demand that only the physically fit and psychologically well adjusted be allowed the privilege of dying for their country.

JOHNSON, A. S. Medicine's Responsibility in the Propagation of Poor Protoplasm. New England J. Med. 238, 22:756 (May 27), 1948.

But It Still Helps—Last November your attention was called to a paper

which pointed out that, although fluorine in the water does reduce caries, it is also helpful to have parents with good teeth. Now comes another paper to warn us that molars are least protected by fluorine, front teeth most. Lower molars are protected only a third.

KLEIN, H. Dental Effects of Community Waters Accidently Fluorinated for Nineteen Years. Pub. Health Rep. 63, 18:563 (Apr. 30), 1948.

Convocation Address—This scholarly discussion of progress of public health from filth diseases to geriatrics ends on this high note. "There is every reason to believe the next 50 years will be at least as fruitful in the medical sciences as the last 50. Probably they will be much more so." To which we can all add a fervent amen.

LONG, E. R. Medical Science and the Longer Life. Science 107, 2778:305 (Mar. 26), 1948.

Sign of Social Maladjustment—Female contagious syphilis has increased ten times during the past eight years in one industrial community, reports a British medical observer. Though male contagious syphilis reveals a welcome fall, an increase in corresponding female statistics is reported throughout England.

MACFARLANE, W. V. Some of the Medico-Social Aspects of Venereal Disease. Pub. Health 61, 8:147 (May), 1948.

A Lot More About Viruses—The most heartening statement in this excellent series of papers is this: practical methods for the diagnosis of many of the viral and rickettsial diseases will be available as soon as the necessary special antigens can be produced. There is a lot more which you should not miss.

SCHULTZ, E. W. Virus Diseases (and five related papers). J.A.M.A. 136, 17:1075 (Apr. 24), 1948.

ASSOCIATION NEWS

SEVENTY-SIXTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
BOSTON, MASS., NOVEMBER 8-12, 1948

FELLOWSHIP IN THE AMERICAN PUBLIC HEALTH ASSOCIATION

The grade of Fellowship was established in the American Public Health Association in 1922. Professional workers in public health are eligible for election as Fellows under certain conditions and as an indication that they have achieved a recognized professional standing. As of January 1, 1948, the total membership of the Association was 11,124, including 1,913 Fellows, or 17 per cent of the total.

Questions are frequently asked regarding the requirements for Fellowship and the following statement outlines the provisions of the By-laws governing qualification and election.

Persons who have been members of the Association for at least two years and who have reached their 30th birthday are eligible to apply if, in their opinion, they meet the conditions of one or more of the six clauses in the By-laws defining "an established professional standing." These six possible approaches are as follows:

a. A person who has rendered acceptable service for two or more years in a responsible public health position and who has been awarded in course a degree of Doctor of Public Health, Doctor of Science in Public Health, Doctor of Philosophy in Public Health, Doctor of Medicine with at least one year of graduate study in public health in a University, Master of Public Health, Diploma in Public Health, or other equivalent

degrees, according to standards approved by the Executive Board of the American Public Health Association.

b. A person who has been awarded in course an academic or professional degree involving training in public health and who has been regularly engaged in health work for at least five years, having rendered meritorious service as a health officer or in responsible charge of work in either a public or private health agency.

c. A person who has done notable original work in public health or preventive medicine of a character to give him a recognized standing.

d. A person regularly engaged in health work for at least five years, who has given evidence of special proficiency, who has attained a recognized standing.

e. A teacher of public health or one of its constituent sciences who has attained distinction as an expounder of the principles of public health or its constituent sciences. Such a teacher shall have had at least five years' experience as a teacher of public health subjects. Any years of experience as defined in paragraphs "b" and "d" that the applicant may have had shall be considered the equivalent of the same number of years' experience as a "teacher."

f. A person not covered by the above, who has made substantial contributions to public health work in his chosen branch, who has attained a recognized professional standing.

Persons wishing to apply should request a Fellowship application blank from the American Public Health Association Membership Department, 1790 Broadway, New York 19, N. Y. Appli-

cations are accepted up to August 1 each year for consideration by the Governing Council at the fall meeting. It is important to make clear that members themselves should take the initiative in submitting such applications. Neither the Sections nor the A.P.H.A. administrative staff are authorized to solicit applications. This means that, although nearly 3,000 persons have been duly recognized with this grade of affiliation since 1922, there are other persons well qualified who have never initiated the process of applying for Fellowship. It should be clear that members should not await action by others if they wish to attain Fellowship. It is necessary and proper for them to take the first step.

An application for Fellowship requires sponsorship by two Fellows of the Section with which the applicant desires to be affiliated. These personal signatures are to be obtained by the applicant before submitting the completed application. The A.P.H.A. office will assist, on request, in determining the Section with which prospective sponsors are affiliated. Applications from persons not wishing to be identified with a particular Section and requesting unaffiliated Fellowship may be sponsored by any two Fellows of the Association.

When properly sponsored and otherwise completed, the application is sent to the A.P.H.A. office, after which the list of persons applying is published in the *American Journal of Public Health*, usually in the September issue, but in any case not less than 15 days before the date for the Annual Meeting. An established routine is followed for review by the Section Councils (unaffiliated applications are reviewed by the Executive Board) and by the Commit-

tee on Eligibility. This Standing Committee of the Association is made up of one Fellow from each of the 12 Sections, plus a Chairman elected by the Executive Board. This group is under instructions from the Governing Council to examine each application in accordance with the provisions of the clause of the By-laws chosen by the applicant, and to apply the criteria with precision in each case. Final election is by the Governing Council at the second meeting at each annual session.

The privileges of Fellowship include eligibility to serve as an officer of the Association or one of the Sections, Chairman of an Association or Section Committee (over one hundred in number), a member of one of the four Standing Committees, a member of the Governing Council or Executive Board, and the right to vote at the Annual Meeting for the elective members of the Governing Council and on amendments to the Constitution. Some Civil Service and merit system records depend upon Fellowship in the American Public Health Association as an achievement deserving recognition in applicants.

The dues of Fellows are \$12.00 annually, and include a subscription to the *American Journal of Public Health* and other services to which members are eligible. Life Membership is available at \$200, covering all future annual dues.

Applications for Fellowship to be considered at the 76th Annual Meeting in Boston, Mass., November 9-12, 1948, should be filed with the Association as soon as they are completed, and in any case not later than August 1. For further information, address the Membership Department, American Public Health Association.

THE 76TH ANNUAL MEETING

Boston, Mass., November 8-12, 1948

Hotel Reservation Form

The hotels listed below have rooms available for Association delegates at the rates indicated. Please note that NO RESERVATIONS WILL BE ACCEPTED DIRECTLY BY HOTELS. Make your reservation through:
The Convention Bureau, Boston Chamber of Commerce, 80 Federal Street, Boston 10, Mass.

| Hotels | Singles | Doubles | Twin Beds | Suites |

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

- Antonio Jorge de Almeida, M.D., Caixa Postal 621, Belem, Para, Brazil, S. A., Health Officer, Servico Especial de Saude Publica
- William E. Amy, M.D., 1801 Ekin Ave., New Albany, Ind., Director, Floyd-Harrison County Health Dept.
- Frederico A. Simoes Barbosa, M.D., M.P.H., Av. Beira Mar 3058, Recife, Pernambuco, Brazil, S. A., Director, Dept. de Saude Publica
- Jackson P. Birge, M.D., Lewis Bldg., Bay City, Tex., Director, Matagordia County Health Unit
- J. F. Holtzmuller, M.D., Court House, Kenton, Ohio, Health Commissioner, Hardin County District Health Board
- Daniel J. Hurley, M.D., State Dept. of Health, Carson City, Nev., Health Officer
- Edward J. Montminy, Health Dept., Berlin, N. H., Health Officer
- Jonas N. Muller, M.D., M.P.H., 760 Market St., Dept. of Public Health, San Francisco, Calif.
- Max Sternlieb, M.D., M.S.P.H., 115½ N. Chestnut St., Ravenna, Ohio, Health Commissioner, Portage County Health Dept.
- Charles F. Thomas, M.D., 3 High St., Caribou, Me., District Health Officer, State Bureau of Health
- Donald W. Tripodi, M.D., M.P.H., 1115 Cedar, Cairo, Ill., Health Officer, Alexander-Pulaski County Health Dept.
- Milton Tully, M.D., 61 Albany Ave., Kingston, N. Y., Apprentice Epidemiologist, Ulster County, State Dept. of Health
- Alonzo S. Verby, M.D., 45 E. 135th St., New York 35, N. Y., Health Officer-in-training, City Dept. of Health

Laboratory Section

- Dorothy M. Adams, 4287 Farlin Ave., St. Louis 15, Mo., Senior Asst. Bacteriologist, St. Louis Health Division Laboratory
- Mary E. Graham, 3215 Southmore, Houston 4, Tex., Bacteriologist-Serologist, Houston City Health Laboratory
- Arthur R. Lack, Jr., M.D., 2103 West 109th St., Los Angeles 44, Calif., Resident in Pathology, Birmingham General Hospital, Veterans Administration, Van Nuys
- Ferdinand Stern, M.D., 8830 West McNichols Road, Detroit 18, Mich., Director, Clinical Laboratories, Marygrove Medical Center, Inc.

Vital Statistics Section

- Katherine Lehman, 523 Paulsen Bldg., Spokane 8, Wash., Medical Record Librarian, Deaconess Hospital
- Barbara M. Lucas, M.N., 8 Edgewood Ave., Apt. 16, New Haven, Conn., Student, Yale Univ. School of Medicine, Dept. of Public Health
- Mary Gwynne Sirls, 1895 Alabama Ave., S. E., Wash. 20, D. C., Medical Record Librarian, Group Health Assn., Inc.

Engineering Section

- Herbert B. Foster, Jr., M.S., 479 Kentucky Ave., Berkeley 7, Calif., Senior Sanitary Engineer, State Dept. of Public Health
- Gilbert M. Golden, 1518 Lafayette, St. Louis, Mo., Sanitary Inspector, Health Division, City of St. Louis
- Warren C. Holm, 704 Fourth St., San Rafael, Calif., Sanitarian, Marin County Health Dept.
- Gomer E. Jones, 1204 Sixth St., Arkadelphia, Ark., Sanitarian, District 3, State Board of Health
- John L. Kent, 3900 53rd Place, Bladensburg, Md., Liaison Information Officer, U. S. Public Health Service
- I. Alvin Pasarew, 4022 Bateman Ave., Baltimore 16, Md., Director, Maryland State Planning Commission
- Theodore Prober, 919 Marybeth Ave., El Monte, Calif., Public Health Engineering Associate, Los Angeles Dept. of Health
- John W. Shipp, Wood County Health Unit, Quitman, Tex., Senior Sanitarian

Millard Knowlton, M.D., Hartford, Conn., Elected Member 1915 (Charter Fellow 1922), Epidemiology Section

THE PROBLEM OF PROPER ILLUMINATION

The Association has been aware of the importance of proper illumination as a concern of public health workers for several years. To the industrial hygienist illumination is an ever present factor for consideration. The school nurse, physician, and teacher are all keenly aware of the need for proper lighting—and for reliable criteria of good lighting. The Subcommittee on the Hygiene of Housing and the Subcommittee on Accident Prevention serve as two other illustrations of the widespread interest in lighting on the part of the Association.

The article by Miles A. Tinker, Ph.D., "Illumination Standards," and the accompanying editorial, "How Many Foot Candles?" which appeared in the September, 1946, issue of the *A.J.P.H.*, brought to a head discussions that had been going on for several years between the A.P.H.A. and the

Illuminating Engineering Society. This Association, representing the professional public health group, and the Illuminating Engineering Society, representing the engineers professionally active in illumination, are two organizations intimately involved in standards of healthful illumination. It was recognized that a joint study of the basic data and their interpretation into standards might be a constructive activity for the two groups. A joint committee composed of representatives from each organization was formed for this purpose. Representatives of the two organizations are:

A.P.H.A.

Leonard Greenburg, M.D.

M. Allen Pond

Donald Y. Solandt, M.D., D.P.H.

I.E.S.

Conrad Berens, M.D.

E. S. Crittenden, D.Sc.

E. M. Strong

C. L. Crouch, Technical Secretary of the I.E.S., serves as a consultant, and Francis B. Elder, Engineering Associate, A.P.H.A., as secretary.

Several meetings of the committee have been held during which Dr. Tinker and Dr. Matthew Luckiesh have met with the committee. Since Dr. Greenburg was also a member of the American Standards Association Sectional Committee on School Lighting, the committee made one of its concerns the matter of illumination for the classroom. As a next step, the committee plans to communicate with those physiologists, psychologists, ophthalmologists, engineers, and others who are currently active in research in the lighting field, inviting consultation on needed research. At the last meeting the following progress report was presented:

"The committee recognized early that an essential difference exists between the approach of the applied and the laboratory scientist. The practising engineer must act on the basis of currently available evidence, while those disciplined in the basic sciences may demand firm proof before action is recommended. However, after hearing the views of both the biological and engineering interests, it was found that their differences were more apparent than real. Where dif-

ferences existed they were found to be due mainly to the fact that different types of tasks were being considered. When the seeing conditions for a given task were specified, it was found that the levels of illumination considered desirable by the two groups were close together and a compromise satisfactory to both was reached.

"As an initial step toward establishing standards, the committee provided Dr. Greenburg with a statement for school lighting (healthy children with normal eyes) to the effect that 'for normal classroom work (reading and writing) there is good evidence that 30 ft.c. properly delivered and maintained is a satisfactory level and, further, that there is no evidence that more than 30 ft.c. would not be useful.'

"It is the opinion of the committee that, whereas standards commensurate with those for schools can be set for other tasks, the experimental evidence at present available is insufficient to justify the recommendation on a scientific basis of an ideal level of illumination for many given tasks. Fundamental research is needed on lighting, on visual phenomena and on their interrelations. This is essential before standards can be established more firmly on scientific fact than on engineering judgment. Toward this end the committee is undertaking the preparation of a list of research projects designed to provide data that will fill the more obvious gaps in present knowledge relating illumination to the visual processes. The committee will encourage other agencies to carry out these projects as the need is indicated."

WESTERN BRANCH A.P.H.A. MEETS IN SALT LAKE CITY

The 1948 meeting of the Western Branch, American Public Health Association was held in Salt Lake City, Utah, May 25-27 under the Presidency of Dr. Florence R. Sabin of Denver. More than 300 persons attended, representing the eleven states of the Branch territory and several of the Canadian provinces. A comprehensive three day program was arranged by a committee under the Chairmanship of Dr. Louis P. Gebhardt of the Department of Bac-

teriology, University of Utah, Salt Lake City. The affairs of the Western Branch were managed by Walter Mangold, Associate Professor at the University of California School of Public Health, Berkeley, Secretary.

Newly elected officers of the Western Branch for the year ending with the 1949 meeting include the following:

President—George M. Uhl, M.D., Health Officer, Los Angeles, Calif.

President-Elect—Arthur L. Ringle, M.D., State Director of Health, Seattle, Wash.

EMPLOYMENT SERVICE

The following pages present information for those seeking qualified public health personnel and for those seeking positions in public health.

This is a service of the Association conducted without expense to the employer or employee.

Address all correspondence to the Employment Service, A.P.H.A., 1790 Broadway, New York 19, N. Y., unless otherwise specified.

(Supplemental to list in June Journal)

POSITIONS AVAILABLE

General Sanitarian whose principal duties will be restaurant sanitation; should have Bachelor's Degree with major in Chemistry or Bacteriology, and a minimum of one year's experience in full-time local Health Department. Post-graduate work of at least one semester in a school of public health desirable. Densely populated county; large, well organized department staff; salary open. Medical Specialist I (Psychiatry) \$545-\$645 per month.

Public Health Physician I (District Health Officer) 4 vacancies, \$545-\$645 per month.

Public Health Physician II (Ass't Chief M.C.H.) \$625-\$735 per month.

Public Health Physician II (Tuberculosis) \$625-\$735 per month.

Public Health Physician II (Venereal Disease and Epidemiology) \$625-\$735 per month.

Write: Personnel Officer, State Board of Health, Madison 2, Wis.

Public Health Opportunities in Connecticut

Openings for epidemiologist; crippled children's physician; child hygiene physician and local health consultant at \$6,300-7,500 salary range. Clinical psychiatrist, salary range \$6,840-8,280. Three years' employment or training including experience in child psychiatry required.

Write: Personnel Department, State Capitol, Hartford, Conn.

POSITIONS WANTED

Health Agency Executive—considerable experience in community organization, voluntary health agency administration and health interpretation desires similar position in East or Middle West. Interested in health or educational agency or industrial organization concerned with planning and promotion of health services and education program. Write Box C-1, Employment Service, A.P.H.A.

Health Educator, male, Negro, M.A., M.P.H., 10 years of health education and teaching in school systems and colleges, 20 months' community health education in a metropolitan area. Interested in community or school health education. Write Box HE-4, Employment Service, A.P.H.A.

Health Educator, Negro, Male, 39. M.S.P.H. (Columbia), 4 years' experience in official health agency. Interested in community health education or health education in schools. Write Box HE-5, Employment Service, A.P.H.A.

Physician, Woman, M.P.H. 1948; 3 years' internship and residency experience; 1 year college health work. Interested in epidemiology, health education, school health, teaching. Write Box Ph-7, Employment Service, A.P.H.A.

Graduate Veterinarian, experienced in disease control work and private practice, desires position in industry and/or public health field. Write Box V-4, Employment Service, A.P.H.A.

Biological and Physical-Chemist, Ph.D. available soon, for Research or Teaching, extensive experience in pharmacology, pharmaceuticals, biologicals, bio-assays. Former university professor, former head, development department of large pharmaceutical manufacturer; 60 publications, many in medical research; books. Executive ability and experience. Age: 35; married; children. Seeks responsible position, educational institution or hospital laboratory. New York Metropolitan area preferred. Answer Box L-2, Employment Service, A.P.H.A.

Recent Graduate Veterinarian (KSC '47) with B.S. degree in bacteriology desires employment. Some experience as a sanitarian. Write Box V-5, Employment Service, A.P.H.A.

Clinician, 12 years' practice in surgery, gynecology, and general medicine abroad and in the U. S. Citizen, male, married. Interested in clinical opening in group practice hospital, industry, or health department. Write Box Ph-4. Employment Service, A.P.H.A.

Dentist, male, 30 years old, single. M.P.H. expected in June, 1948. Three years' experience in clinical and administrative work. Interested in administrative dental opening with or without clinical responsibilities. Write Box D-1, Employment Service, A.P.H.A.

Veterinarian, M.P.H. degree; 2 years' experience federal meat inspection; 2 years teaching milk hygiene and assistant in bacteriology in large university. Interested in public health openings. Will consider full-time positions (or part-time with practice opportunities) in state or local work, agencies or institutions. Available between July 1 and August 1. Write Box V-3, Employment Service, A.P.H.A.

Sanitary Engineer, B.S., M.S., M.P.H.; seven years' experience with State Health Department; three years in Army Sanitary Corps; two years in industry, desires position in public health engineering. Write Box E-4, Employment Service, A.P.H.A.

Bacteriologist, M.S., minor chemistry, 9 years' extensive experience in research, clinical bacteriology, and industrial development. Interested in responsible position in public health, industrial laboratory, or teaching institution. Write Box L-D-1, Employment Service, A.P.H.A.

Health Educator, female, six years' experience in community organization for health with voluntary agency; 5 years' experience as supervisor of a community health center; 5 years' experience in university health service, R.N., B.S. Seeks opportunity in health education or administrative opening. Write Box H-E-3, Employment Service, A.P.H.A.

Physician, woman, considerable experience in practice of pediatrics and school health administration, consultant to professional and voluntary agencies, desires interesting position part or full time in greater New York area. Write Box Ph-6, Employment Service, A.P.H.A.

(c) Assistant professor of public health nursing; collegiate school; \$4,000–\$5,000; additional income for summer teaching. (d) School nurses; health department of public school system; \$2,600–\$3,000; additional experience or training increases salaries to \$4,200; short distance from Chicago. (e) Clinic nurses; student health department; large university; winter resort area of the South offering many cultural advantages. **PH7-1** Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago 11.

WANTED—(a) Physician to direct student health department; approximately 9,000 on campus; excellent facilities; unusual opportunity for developing program. (b) Public Health Physician for appointment as State Commissioner of Health; Master's or Doctor's degree in public health medicine with minimum of five years' experience; \$12,000. (c) Physician trained and experienced in infant care to direct maternal and child health services, municipal department of health; newly created position unim-

peded by politics; woman eligible; Middle West. (d) District health officer; duties consist of directing county health department and developing program; \$7,400–\$9,100; Pacific Coast. (e) Assistant Director, Student Health Department; state supported university; approximately 6,000 students; expansion program; \$7,500; South. **PH7-2** Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago 11.

WANTED—(a) Health Educator to work with colleges and educators; preferably one who has taught Health Education in a teachers' college, willing to travel; East. (b) Sanitarian; health department serving three counties; Michigan. (c) Two nutritionists; state department of health; salary dependent upon experience. (d) Two young women, Ph.D.'s or M.D.'s for academic appointments; university having highly organized program of professional training in health field for teachers; one should be qualified in teaching correctives; other in health education; students, undergraduates, and graduates; ranks dependent upon qualifications. (e) Sanitary Chemist, with working knowledge of chemistry of water and sewage; experience in water filtration plants and sanitary engineering laboratories advantageous; health department of modern community, new research institution; \$4,900–\$5,900; Southwest. (f) Health educator; middle western city of 40,000; \$4,500–\$5,000. **PH7-3** Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago 11.

Opportunities Wanted

Dentist—Experienced in public health work is available; several years' private practice limited to children's dentistry; past six years, public health dentistry. For further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago, Ill.

Health Educator—M.P.H., Yale, three years, health teacher in elementary schools; several years, health educator city health department. For further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago, Ill.

Public Health Nurse is available for administrative position; M.A. public health nursing; six years, educational supervisor, city health department; eight years, nursing consultant, state board of health. For further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building Chicago, Ill.

Public Health Physician; medical degree, eastern school; M.P.H. Harvard; six years, director county

health department; in '38 reorganized city health department and remained as its director; teaching experience; available for relocating because of desire for broader administrative responsibilities. For further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago, Ill.

Sanitary Engineer; Bachelor of Science in Civil Engineering, Major in Sanitary Engineering, Master's in Public Health Engineering; ten years, director, department of engineering, state department of health; duties include responsibility for entire environmental sanitation in public health engineering program for a population of over a million. For further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago, Ill.

Student Health Physician, B.A., B.S., M.P.H., M.D. degrees, eastern schools; eight years, director, student health department, state university. For further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago, Ill.

NEWS FROM THE FIELD

NATIONAL CONFERENCE ON FAMILY LIFE

The background of the National Conference on Family Life was given in the *March Journal* (p. 453). Held in Washington May 6-8, with about 900 persons representing 125 sponsoring agencies, it explored ten areas of current American life that affect family living and that need to be properly used to protect and strengthen family relations. Representatives were present from 30 countries in addition to the United States.

The 10 areas considered were community participation, counselling and guidance, economic welfare, education, health, home management, housing, legal problems, recreation and social welfare. Co-chairmen of the health section were Leona Baumgartner, M.D., and Haven Emerson, M.D. This section was chiefly concerned with measures to assure families of adequate health and medical services at all stages of the family cycle.

Delegates in the housing section, whose concern was adequate housing for a safe, healthy, and wholesome family life endorsed the Taft-Ellender-Wagner Bill, including its public housing program. The education groups placed particular emphasis on training and personal help for marriage and family problems for high school boys and girls.

A feature of the conference was a plenary session addressed by President Truman. Speaking extemporaneously he urged the delegates to use their influence in getting the housing bill passed and pointed out the close relationship between a happy and prosperous America and world peace.

Eric Johnston served as Chairman of the Conference. In his closing address, he said in part:

"Never before in the history of America has so much solid and constructive thinking been devoted to the position of the family in America. You who came here and gave so generously of your skills and your time are responsible for this happy result.

"What we have done here will be largely lost unless the work of this Conference is translated into programs of action on the local level. The problems of the family—in everything that these problems imply and entail—can be most effectually met in the community where the family lives. There are obvious areas for national action but the major efforts must be in the community.

"On your return home, I hope that you will take appropriate steps to establish Community Councils on Family Life. This conference has set standards and patterns for such councils. The councils should embrace every group and organization whose activities touch on the problems of family living."

The *Survey Midmonthly Magazine* of June reported the highlights of the conference in a special section entitled "Security in Family Life; Threats and Opportunities." This includes a discussion guide for club leaders. It is available in a 16 page reprint from *Survey Midmonthly*, 112 East 19th St., New York 3, at 15 cents per copy; 10-99 copies 12 cents; 100 copies or more 10 cents.

MIDCENTURY WHITE HOUSE CONFERENCE ON CHILDREN

At a meeting of the National Commission on Children and Youth in Washington in January, preliminary plans were discussed for a 1950 White House Conference on Children and Youth. This would be the fifth such decennial conference.

Previous White House Conferences on Children have served as "starters" for state and local action on objectives agreed to by the National Commission.

This time the commission recommends a new and reverse approach: That

the 1950 meeting come as a climax to a 2 year preparatory program of action in states and communities so that the 1950 conference can count gains made and plan for the next decade.

It recommended that the conference place its primary emphasis on "The Child in His Family and Community." It would be planned to evaluate progress since 1940, to assess the status of services and opportunities provided children, and to stimulate the achievement of a greater measure of security and opportunity for all children.

The 2 year program of preparation suggested would include (a) action by states and communities and (b) a national program of research with state cooperation.

The preliminary planning of the commission for the 1950 conference was reported in *The Child*, March, 1948. Reprints are now available from the Government Printing Office, Washington 25, D. C. The U. S. Children's Bureau also has prepared a mimeograph summary of the early planning meeting, which is available on request.

CONFERENCE ON SCHOOL HEALTH PROPOSED

The maternal and child health section of the recent National Health Assembly advocated a major attack on the school health problem. The report, drafted by a steering committee headed by Leona Baumgartner, M.D., Director of the Division of Child Hygiene of the New York City Health Department, asks the Federal Security Administrator to call a national conference on school health with a particular view to getting health and education departments to work together. The report indicates that the problem of administrative responsibility for school health services has been a major stumbling block to their adequate development and that the concept of single agency responsibility must be replaced by joint plan-

ning and mutual recognition of respective responsibilities.

SOCIAL HYGIENE LIFE MEMBERSHIP TO DR. HALVERSON

Wilton L. Halverson, M.D., was presented with honorary life membership in the American Social Hygiene Association at the Social Hygiene Institute of San Francisco in March. The Institute was held jointly by the American Social Hygiene Association, its San Francisco Chapter, and the San Francisco Health Department.

In making the award, the Association issued the following statement:

"Wilton L. Halverson, Physician, Public Health administrator and educator, from the beginning of his brilliant career, has been a strong friend and dependable ally of local, state, and national social hygiene work.

"As a physician, he has required the highest standards of medical care for the victims of syphilis and gonorrhea. As a public health administrator, he has instituted in local and state agencies and encouraged nationally the comprehensive modern attack on the venereal diseases with medical, educational and social weapons. As an educator, he has taught preventive medicine with due regard for the social factors in health and disease.

"His qualities of leadership, his wisdom and his generosity have raised him in a comparatively few years to a position of highest distinction among public health workers.

"Grateful for his never-failing support and in recognition of his outstanding service, the Committee on Awards is pleased to confer on Dr. Halverson, Honorary Life Membership in the American Social Hygiene Association."

NEW FILM ADVISORY SERVICE

A film advisory service for medical, public health, and welfare organizations was inaugurated in May by David Resnick, Public Relations Counsel, 1775 Broadway, New York City. The service furnishes advice in the planning, production, and distribution of non-theatrical motion pictures and slide films.

Mr. Resnick's consultants include Maurice Feuerlicht, former Director of Medical and Health Films for the Office of the Coordinator of Inter-American

Affairs; Edward F. Kerns, Technical Director of the Museum of Modern Art Film Library; and William S. Resnick, film writer and director.

SAFETY FILM OSCARS

The National Committee on Films for Safety, representing 17 national organizations interested in safety, including the American Public Health Association, recently awarded Safety "Oscars" to three motion pictures and three sound slidefilms for their outstanding contributions to safety in 1947. Five films received honorable mention. The awards are made annually in three fields of safety—traffic, occupational, and home and general.

In the general safety field, "Safety Our No. 1 Crop," produced for General Motors Corporation (1775 Broadway, New York 19) by Sound Masters Inc., was judged the best motion picture. This has been described as a pastoral treatment of farm safety pointing out the hazards and the safety practices that overcome them. Among sound slidefilms top honors were won by "The Fire Bug" produced by the Atlas Educational Film Co. for the Zurich Insurance Company (135 South LaSalle St., Chicago). Honorable mention was given to "Danger Is Your Companion," a motion picture produced by the American National Red Cross, (Washington, D. C.). This emphasizes first aid as a means of keeping minor injuries from becoming serious.

In the occupational field the motion picture winner was "Diagnosis—Danger" produced for St. Paul-Mercury Indemnity Co., (111 W. 5th St., St. Paul 2) by Chicago Film Studios. This depicts a hospital superintendent whose eyes were opened to accident hazards in his own hospital when he broke his leg falling down its marble stairs. The slidefilm adjusted best is "Fifteen Minutes to Go," produced for the National Safety Council (20 N. Wacker

Drive, Chicago) by Sarra Inc. Also receiving honorable mention were the motion picture "Use Your Head," produced by the Denver, Rio Grande and Western R.R. (Denver, Colo.) and the sound slidefilm "Falling Ground" produced by Anaconda Copper Mining Co., (25 Broadway, New York).

In the traffic field, no motion picture award was made. "Destination — Death," produced by Burton Holmes Films, Inc. for Zurich Insurance Company, was judged the best sound slidefilm. The motion picture, "Live and Let Live," produced by Aetna Casualty and Surety Co. (Hartford, Conn.) received honorable mention.

The theatrical motion picture on safety judged best is "Going to Blazes" produced by Herbert Morgan and released by Metro-Goldwyn-Mayer. It is described as thrilling and a good send-off for a fire prevention program.

For information as to purchase, loan, or showing of these films, inquire from individual producers.

WHO WORLD AGENCY FOR VITAL STATISTICS

Convening in Paris late in April at the call of the French Government, the International Conference for Revision of International Lists of Diseases and Causes of Death decided to transfer to the World Health Organization all responsibility in the field of international vital and health statistics. Thirty countries participated in the Conference and recommended a program to make available comparable health statistics collected the world over and thus facilitate the study of health problems. National committees for the purpose of coordinating statistical activities within countries were recommended as was a program of medical statistical research. It is expected that the World Health Assembly will appoint an Expert Committee on Health Statistics to carry out this program.

MEETINGS OF AFFILIATED SOCIETIES OF THE A.P.H.A.

Colorado Public Health Association—"TOGETHER Let's Make Colorado First in Health" was the theme of the Colorado Public Health Association's Annual Meeting held in Denver on May 21 and 22. The discussions and panels were centered around problems and progress in Colorado, and the speakers were drawn from field workers. The Florence R. Sabin Award for "outstanding contribution to the health and well-being of the people of Colorado" was presented to Dr. Solomon S. Kauvar. Officers to serve for the ensuing year were elected as follows:

President—Mary H. Emberton, R.N., Denver
Vice-President—John A. Brown, Colorado Springs
Treasurer—Norma Johannis, Denver
Secretary—Sara Lou Harrison, Denver

Connecticut Public Health Association—This society met on May 12 to honor Stanley H. Osborn, M.D., for his service as Commissioner of Health during the past 25 years. "Stanley H. Osborn Day" was developed by the faculty of the Department of Public Health of Yale University. Registration for the day-time meeting was 212. The program was highlighted by an unusually fine exhibit depicting Connecticut's Health History in Vital Statistics. Richard O. Shea, M.D., was selected as the new representative on the A.P.H.A. Governing Council and the following officers were elected:

President—George B. Davis, M.D., Norwalk
President-Elect—Sterling P. Taylor, M.D., North Haven
Vice-President—Benjamin N. Pennell, D.V.S., New London
Secretary-Treasurer—Muriel F. Bliss, Ph.D., Hartford

Georgia Public Health Association—The Georgia Public Health Association held its 19th Annual Meeting in Savannah May 10-12, at which time the following officers were elected:

President: Clair A. Henderson, M.D., Savannah
President-Elect: James A. Thrash, M.D., Columbus
Vice-President: F. W. Rhodes, Rome
Secretary-Treasurer: Annie J. Taylor, Atlanta
Representative on A.P.H.A. Governing Council: M. E. Winchester, M.D., Brunswick

The three days of meetings included sessions of the Medical Officers, Public Health Engineering, and Public Health Nursing Sections, three General Sessions, and one Special Session entitled "A Governor Looks on Public Health," the address being presented by the Hon. M. E. Thompson, Governor of Georgia.

Idaho Public Health Association—The 9th Annual Meeting of the I.P.H.A. was held on May 3 and 4 in Coeur d'Alene. The overall theme was "Idaho Health Problems by Idaho Speakers" and included such subjects as Complete Local Health Service Coverage, Organizing Community Activity with Respect to Health, Blood Banks, Cancer, Tuberculosis, Hospital Programs, Dental Problems, Venereal Disease Control, Prepaid Medicine, and Poliomyelitis. The following new officers were elected:

President—Mrs. Grant Hess, Boise
1st Vice-President—Etta Lee, R.N., Idaho Falls
2nd Vice-President—Sister M. Alma Dolores, Boise
3rd Vice-President—J. A. Rice, D.D.S., Coeur d'Alene
4th Vice-President—Mrs. John E. Hayes, Twin Falls
5th Vice-President—R. L. White, M.D., Boise
Secretary—A. W. Klotz, Boise
Treasurer—Frances M. Goodwin, Boise
Representative to the Governing Council of A.P.H.A.—Lawrence J. Peterson, Boise

Iowa Public Health Association—A registration of 138 has been reported for the Annual Meeting of the Iowa society held in Des Moines on May 27 and 28. Several panel sessions were held with gratifying audience participation. The following officers were elected at the annual business session:

President—Carl C. Potter, Des Moines

President-Elect—I. H. Borts, M.D., Iowa City

Vice-President—Sophie Fevold, R.N., Des Moines

Secretary-Treasurer—Loren Chancellor, Des Moines

Kansas Public Health Association—

Following what has now become an annual custom, the Kansas Public Health Association selected an honor guest for its 1948 annual meeting held in Topeka in April. He is C. H. Lerrigo, M.D., for 26 years Executive Secretary of the Kansas Tuberculosis and Health Association, and currently Secretary Emeritus.

Among the speakers at the three day meeting were Reginald M. Atwater, M.D., A.P.H.A.; Leroy E. Burney, M.D., Indiana State Health Officer; and J. O. Dean, M.D., Medical Director of U. S. Public Health Service District 7.

Officers elected for the coming year are:

President: M. Leon Bauman, M.D.

President Elect: James M. Mott, M.D.

Secretary-Treasurer: Evelyn Ford

Missouri Public Health Association—

At its 22nd Annual Meeting held in St. Louis May 12 to 14 the Missouri Public Health Association elected the following new officers to serve for the forthcoming year:

President—Alexander E. Murphy, D.D.S., St. Louis

President-Elect—J. Earl Smith, M.D., St. Louis

First Vice-President—Ida E. Gutschke, R.N., Springfield

Second Vice-President—A. R. Baron, Fredericktown

Treasurer—John Buxell, St. Louis

Secretary—L. E. Ordelheide, Jefferson City

Representative to A.P.H.A. Governing Council—Joseph C. Willett, D.V.M., St. Louis

Representative to Southern Branch A.P.H.A. Governing Council—John W. Williams, Jr., M.D., Jefferson City

Several meetings were held by the Laboratory, Health Officers, Engineer-

ing, Vital Statistics, and Nursing Sections, and one day was devoted to important General Sessions in the morning, afternoon and evening.

New Mexico Public Health Association—

The 20th Annual Meeting of the New Mexico Public Health Association was held at Las Cruces May 20 to 22 inclusive. Participating in this meeting were Dr. J. L. Troupin of Columbia University School of Public Health, representatives from the State Health Departments of Arizona and Texas, and officials from the El Paso office of the Pan American Sanitary Bureau and the International Boundary and Water Commission. Officers for the forthcoming year were elected as follows:

President—Eunice L. Vandervoort, Sante Fe

Past President—C. E. Kaufman, M.D.

President-Elect—H. D. Newman, M.D., Clovis

Vice-President—Geraldine M. Beery

Secretary-Treasurer—Leon duFlon, Albuquerque

Mrs. Hazel Losseff was reelected delegate to the Western Branch, A.P.H.A., and James R. Scott, M.D., was continued as official representative to the A.P.H.A. Governing Council with Myrtle Greenfield as alternate.

Tennessee Public Health Association

The Tennessee society held its Annual Meeting in Nashville May 3, 4, and 5. The theme of the general session was Health Education, with four excellent papers on the program. The sectional meetings were well attended and good papers were presented. New officers were elected as follows:

President—Helen Jean, R.N., Johnson City

Vice-President—Dick C. Thompson, Nashville

Secretary-Treasurer—Munroe F. Brown, M.D., Nashville

The Executive Committee reelected John J. Lentz, M.D., to represent the society on the A.P.H.A. Governing Council.

WALTER REED IN THE HALL OF FAME

On May 20 the bust of Walter Reed, M.D. (1851-1902) was unveiled in the Hall of Fame, New York University, of which he was an alumnus. The bust, sculptured in bronze by Cecil Howard, was unveiled by Dr. Reed's son, Major General Walter L. Reed, U.S.A. Rt.

Dr. Reed, as the conqueror of yellow fever, was elected to the Hall of Fame at the last meeting of the election committee in 1945. He missed election by only four votes in 1935. Nominees are not eligible for consideration until at least 25 years after their death. The Hall has niches for 150 busts, of which more than half are filled.

Dr. Reed organized the Yellow Fever Board when an epidemic of yellow fever broke out among American troops in Cuba during the Spanish-American War. Proving through intensive investigation that the disease was carried by the mosquito, as had been argued by Dr. Carlos J. Finlay for 20 years in the face of professional ridicule, Dr. Reed checked the epidemic in a short time by instituting an island-wide sanitation campaign to destroy mosquito infested areas.

Dr. Reed, who joined the American Public Health Association before the turn of the century, presented a preliminary report of the Yellow Fever Board and its investigations at the Association's 29th Annual Meeting in Indianapolis in 1900. A later paper at the American Medical Congress in 1901 presented further evidence, based on

controlled experiments in which volunteers subjected themselves to possible infection.

At the 62nd Annual Meeting of the Association in 1933, also in Indian-

apolis, a special memorial banquet to Dr. Reed and his Associates on the Yellow Fever Board was held at which addresses were made by Major General Robert U. Patterson, Surgeon General, U.S.A. (*A.J.P.H.*; Vol. 23, p. 1127) and Frederick F. Russell, M.D., of the International Health Division of the Rockefeller Foundation (Vol. 34, p. 1). Present also were four of the volunteers who submitted to the bites of infected mosquitoes as a part of Dr. Reed's experiments.

NEW UNION HEALTH CENTER

Plans for a new \$1,000,000 labor union health center in New York City were announced jointly by the Amalgamated Clothing Workers, CIO, and the New York Clothing Manufacturers Exchange at the annual meeting of the former in May. The health center

is expected to be in operation by September. The annual operating budget of \$500,000 will be contributed by employers and the center will be administered jointly by the employers and the union.

The center in New York will be the forerunner of similar centers to be es-

tablished in Chicago and Philadelphia. These centers will supplement the benefits Amalgamated members receive under their industry-wide health insurance program.

The Union Health Center of the International Ladies' Garment Workers in New York City celebrated its 30th year in 1947 by enlarging its quarters and services. Similar union health centers are in operation in other cities, notably Detroit and St. Louis.

INDIANAPOLIS-MARION COUNTY HEALTH UNIT URGED

The *Indianapolis News* of April 28 reported action by the health section of the Indianapolis Council of Social Agencies urging legislation to permit setting up a combined Indianapolis-Marion County Health Department. At present Indianapolis, which has more than four-fifths of the county's population of approximately half a million, has a health department under the full-time leadership of G. F. Kempf, M.D. The remainder of the county is without the services of a full-time health officer.

U.S.P.H.S. ESTABLISHES "SANITARIAN" CATEGORY IN THE REGULAR CORPS

The category of "Sanitarian" has been established by the Surgeon General of the U. S. Public Health Service upon recommendation of the Central Personnel Board. It will be a restricted category, at a grade still to be finally determined. The Regulations Board is recommending that the senior grade be restricted which, if approved, would mean that length of service promotions would be made up to and including the full grade.

In addition to the qualifications prescribed in the Regulations for all candidates, applicants for appointment as sanitarian officers in the Regular Corps are required to possess the following:

- A. For the Assistant Grade seven years of education and experience (exclusive of

high school) are required and must include the following:

1. A baccalaureate or equivalent degree from an institution of recognized standing, with emphasis on one or more of natural or social sciences as follows:
 - (a) Bacteriology, biology, parasitology, entomology, chemistry, physics, psychology, mathematics, nutrition
 - (b) Sociology, government, economics, public administration, and education
2. Satisfactory completion of one year of postgraduate study in a school of public health approved by the American Public Health Association, with a master's degree in public health or its equivalent. In the case of a candidate in the natural sciences a master's degree in natural sciences may be substituted for the graduate degree in public health.
3. One year of experience which, in the opinion of the examining board, would qualify the candidate to perform the duties of an officer in the special field.
- B. For the junior Assistant Grade all of the qualifications listed above are required except either A 2 or A 3.
- C. For grades above Assistant Grade all qualifications specified in paragraph A are required, in addition to those to be specified for higher grades in Regulations.

GRADUATE TRAINING IN SANITARY AND PUBLIC HEALTH ENGINEERING, UNIVERSITY OF MISSOURI

New classes in engineering and in other departments of the University of Missouri have been established to meet modern requirements for graduate work in sanitary and public health engineering. The new program, developed in consultation with leaders in the educational, consulting, and public health fields, is directed by Professor Lindon J. Murphy of the university, and W. Scott Johnson, Chief Engineer of the Missouri State Board of Health. In order to make the program more effective, an undergraduate sanitary engineering option in the Civil Engineering Department has also been developed.

Candidates for graduate degrees must fulfil the usual requirements for admission to the Graduate School, which include a bachelor's degree in engineering from a school of recognized standing.

Candidates for the degree of Master of Science are required to complete two semesters of graduate study. Many of the courses will be offered during the summer session.

Further information can be obtained from Harry A. Curtis, Dean, College of Engineering, University of Missouri, Columbia, Mo.

AMERICAN CANCER SOCIETY'S ADVISORY NURSING COMMITTEE

A Nursing Advisory Committee on nursing care for cancer patients has been created in the American Cancer Society. The committee is made up of representatives of seven national nursing organizations and three institutions with a leading role in cancer nursing. This committee, whose chairman is Katharine R. Nelson of Teachers College, Columbia University, functions under the medical and scientific division of the society and reports to the education committee of the Board of Directors.

At the first meeting of the committee in New York in April the committee outlined its purpose as (1) to help in the development and use of materials being prepared for nurses, and (2) to help develop new program ideas as suggested by needs in the field.

To further these purposes an editorial committee to advise on a new *Manual on Cancer Nursing* was appointed as was a film committee to advise on the production of a series of three 15 minute teaching films on cancer nursing.

Also announced at this meeting was a new exhibit for nurses which emphasizes the nurse's responsibility in cancer control and the importance of early detection. This exhibit, using transparencies, was first shown at the recent Biennial Nursing Convention in Chicago. It is

available on loan to professional groups, public health and other agencies, without charge. Write Marjorie Schlotterbeck, Nursing Consultant, American Cancer Society, 47 Beaver St., New York 4.

TRI-COUNTY HEALTH DISTRICT IN COLORADO

The *Colorado Health News* reports that the Tri-County Health Department, comprising Adams, Arapahoe, and Jefferson Counties (1940 population, 85,000), is the first district unit to begin operation with a full staff in both central and district offices.

The Medical Director is Marion McCallum, M.D. The central office is at the University of Colorado Medical Center in Denver, and there is a sub-center in each of the three counties.

WATER AND SEWAGE WORKS DATA

The April, 1948, issue, Vol. 95, No. 4, of *Water and Sewage* includes the annual reference and data section on water and sewage works for 1948. These data are presented in two general sections; one on water supply and one on sewage treatment. The material was prepared by Dr. George E. Symons.

FLUORIDE THERAPY IN KANSAS

The Kansas State Board of Health, through its Division of Dental Hygiene, is distributing to all practising dentists who request it, a 2 per cent aqueous solution of sodium fluoride together with instructions for use. Its purpose is to make this treatment available to all desiring it.

This phase of fluoride therapy has been proved effective in reducing dental decay 40 to 50 per cent in school children. The procedure recommended to the dentist entails cleaning of the teeth, thoroughly drying them, applying a 2 per cent solution of sodium fluoride to all surfaces and allowing to dry 4 minutes. Application of the solution is re-

peated three times at intervals of one day to one week.

More than a third of the dentists in Kansas have received the solution. The treatment is not recommended in areas where the water supply contains adequate amounts of fluorides.

RESOLUTION IN MEMORY OF DR. WADE H. FROST

At its spring meeting on April 30 in New York, the Executive Board of the American Public Health Association adopted the following Resolution in recognition of the anniversary of the passing of Dr. Frost on May 1, 1938:

The Executive Board of the American Public Health Association is reminded that ten years have now passed since Dr. Wade Hampton Frost died May 1, 1938.

Although a decade is usually sufficient to obliterate much of the personality and influence of ordinary men, in the case of Dr. Frost it is now even more evident than in 1938 that he influenced his generation in lasting ways. He not only established a point of view and a characteristic method of scientific work, but he brought up young men to carry on the tradition so well established.

The Executive Board has reason to recall the contribution which he made to this professional society. He was Chairman both of the Laboratory and of the Epidemiology Sections and for many years was a prominent member of the Governing Council. In 1948 there has been reprinted his carefully formulated statement on Authoritative Standards and Association Policy which he presented at a meeting of the Executive Board on December 19, 1935. It is well for a new generation to catch the breadth and precision of his thought.

The Board wishes on this occasion to send this word of appreciation and respect to Mrs. Frost and to repeat the words written ten years ago, "Those who were privileged to have his friendship find their sorrow embedded in deep thankfulness."

On the tenth anniversary of Dr. Frost's death, Dr. Reginald M. Atwater, Executive Secretary, presented the above Resolution to Mrs. Frost at her home — 508 Woodlawn Road, Baltimore, Md., together with nearly fifty letters in tribute to Dr. Frost from his former students and associates.

ARIZONA HEALTH EDUCATION WORKSHOP

The Arizona State College, Flagstaff, with the coöperation of 18 state and national agencies, announces a Health and Safety Education Workshop August 2-14, with daily programs from 7 A.M. to 4:15 P.M. Among the Consultants will be Dr. Clair E. Turner of the National Foundation for Infantile Paralysis, and Vivian Drenckhahn of the National Tuberculosis Association.

The Workshop rate of \$35 covers room and board for the two weeks. Applications should be filed with the Registrar, Arizona State College, Flagstaff, not later than July 15.

ONE YEAR OF THE NEW YORK HEALTH COUNCIL

The Health Council of Greater New York celebrated its first birthday with a luncheon on May 19, attended by about 300 guests. The guest speaker was Bleecker Marquette, Executive Secretary of the Cincinnati Public Health Federation, who told of some of the achievements—as well as some of the failures—of Cincinnati's quarter of a century old health council.

The meeting also heard a report from Dr. E. H. L. Corwin on the survey of health needs and services in New York. This study is being made by the Council in coöperation with the New York Academy of Medicine's Committee on Public Health Relations. The joint committee directing the study includes, in addition to Dr. Corwin as Chairman, Drs. Thomas D. Dublin, Haven Emerson, Henry E. Meleney, Harry S. Mustard, and Wilson G. Smillie and Mr. David Heyman.

Newly elected officers of the Council:

President: I. Ogden Woodruff, M.D.

Vice Presidents: Mrs. Sidney C. Borg, Thomas D. Dublin, M.D., Mrs. Jose Ferrer, Roderrick Stephens

Treasurer: Harry P. Davison

Assistant Treasurer: Mortimer J. Gleason

Secretary: Fred M. Stein

WATER AND SEWAGE WORKS MANUFACTURERS ELECT

At the Annual Meeting of the Water and Sewage Works Manufacturers Association, Inc., the following officers were elected to take office on January 1, 1949:

President: Willard F. Rockwell, Chairman, Board of Directors of the Rockwell Manufacturing Company

Vice-President: Reginald F. Hayes, Vice-President and General Sales Manager, Hydraulic Development Corporation

Treasurer: Edgar J. Buttenheim, President, The American City Magazine Corporation

Secretary-Manager: Arthur T. Clark

ACADEMY OF SCIENCES NAMES MEDICAL MEN

The following medical scientists were among those whom National Academy of Sciences honored with elections to membership at its annual meeting in Washington in April: Eric G. Ball (Harvard), Hallowell Davis, (Washington, St. Louis), Karl Folkers (Merck & Co.), Thomas Francis, Jr., (Michigan), Haldan K. Hartline (Penn.), Frank L. Horsfall, Jr., (Rockefeller Inst.), Raymond A. Kelser (Penn.), Cyril N. H. Long (Yale), and James B. Sumner (Cornell). The only woman elected this year, and the fourth in the Academy's history, was Dr. Gerty T. Cori, fellow and research associate in pharmacology and biochemistry at Washington University School of Medicine (St. Louis).

DIRECTORS OF LOCAL HEALTH SERVICES MEET

The second annual meeting of the Association of State and Territorial Health Officers was held at the Lake of the Ozarks, Missouri, on April 22 and 23. The 25 directors of local health services who attended discussed on an operating level the many common problems of local health administration. Among these were the Local Health Services Act of 1948, Special Services as a Part of Local Health De-

partment Programs, a panel led by Roscoe P. Kandle, M.D., Field Director of the American Public Health Association, and Making Local Health Service Attractive.

Richard Boyd, M.D., reported on the Princeton Conference and R. N. Barr, M.D., on the National Conference on Rural Health.

The following officers were elected:

President: John W. Shackelford, M.D., Oklahoma

Vice President: V. A. Van Volkenburgh, M.D., New York

2nd Vice President: John W. Williams, Jr., M.D., Missouri

Councilor: John K. Altland, M.D., Michigan

Councilor: Ellis D. Sox, M.D., California

Secretary: Trois E. Johnson, M.D., Louisiana

DR. GEBHARD IS HONORED

Bruno Gebhard, M.D., director of the Cleveland Health Museum, was awarded honorary fellowship for "his untiring efforts in the field of public health education" by the Board of Commissioners, Rochester, N. Y., Museum of Arts and Sciences. The citation reads in part:

"Bruno Frederic Gebhard, physician, museum director and outstanding authority in the field of public health exhibits. As founder and head of the first museum of its kind in the western world, the Cleveland Health Museum, this versatile scientist has spent the greater part of his life making health visible."

ENGLISH SUMMER SCHOOL IN HEALTH EDUCATION

The Central Council for Health Education (London) will hold its annual Summer School in Health Education at "High Leigh," Hoddesdon, Hertfordshire, August 11-25, 1948. There are still a few places not yet taken, and educational and medical administrators, doctors, teachers, youth leaders, public health nurses, industrial nurses, industrial welfare workers, training or-

ganizers, and students may apply at once for further details to The Medical Adviser and Secretary, The Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.I.

NINTH INTERNATIONAL CONGRESS ON INDUSTRIAL MEDICINE

Announcements have been made from London that the Ninth International Congress on Industrial Medicine will be held at Caxton Hall, Westminster, London, September 13-17, 1948. This is the first international congress of its kind to be held in ten years, and it is hoped that representatives from at least twenty-two countries will attend. The special interest of the congress will be with the recent advances in the practice of industrial medicine and research into many of the facets of modern industrial life.

The American Public Health Association has been invited to name a delegate, and Fellows or members of the Association who expect to attend the congress are asked to communicate with the Executive Secretary, A.P.H.A., 1790 Broadway, New York 19.

EMPLOY THE HANDICAPPED WEEK

The American Federation of the Physically Handicapped has announced the date for the 1948 national Employ the Physically Handicapped Week for October 3-9. Such a week was first observed in 1945, the inspiration of Paul A. Strachan, himself handicapped by total deafness. For further information inquire of American Federation of the Physically Handicapped, 1376 National Press Building, Washington 4, D. C.

U.S.P.H.S. CREATES HEALTH EMERGENCY PLANNING UNIT

Dr. Leonard A. Scheele, Surgeon General, recently signed an order creating a Health Emergency Planning Unit in

the Public Health Service. According to the *Washington Report on the Medical Sciences*, the function of the new Section is to deal with both public and private agencies in matters relating to public health preparedness against attack or invasion. Dr. Norvin C. Kiefer, Senior Surgeon, has been placed in charge of the Unit with instructions to work closely with the National Security Resources Board, the Office of Civil Defense Planning, other official, federal and state organizations, and with professional and voluntary organizations interested in protection of civilian health.

PERSONALS

Central States

JOHN MACKENZIE CORY has been appointed Executive Secretary of the American Library Association with headquarters in Chicago. Currently Associate Librarian of the University of California Library, he will take his new office September 1, succeeding CARL MILAM who recently became Director of United Nations Libraries.

BEN D. KININGHAM, JR.,† was appointed Executive Secretary of the Illinois Tuberculosis Association effective in April. He succeeds the late W. P. SHAHAN.† Mr. Kinningham was formerly Health Education Director of the Illinois Association.

EARL G. LIPPENCOTT† has joined the staff of the United Health and Welfare Fund of Michigan in Lansing as Secretary to the Admissions and Budget Committee, and serving in the field of agency relationships. Mr. Lippencott has most recently been a research associate in the Russell Sage Foundation, New York City, and earlier was a regional representative of the Social Protection Division, Federal Security Agency.

THOMAS F. MOONEY,† formerly head hygienist of the Ford Motor Company, has opened an industrial hygiene laboratory specializing in analysis such as urinary or other atmospheric lead, also biological fluorides, dust counts, and other specialized analysis. The laboratory is called MED-FAC Laboratories, the address is 4617 Allen Road, Allen Park, Mich.

OLIN W. MORRIS, D.V.M., Assistant Chief Veterinarian, Kansas State Board of Health, was recently elected Secretary of the Kansas Medical Veterinary Association, and also was appointed to the State Board of Veterinary Examiners by GOVERNOR CARLSON.

Eastern States

CHARLES O. BRADLEY, M.D., previously Director of the Emma Pendleton Bradley Home for the study of atypical children in East Providence, R. I., recently became Director of the Joint Child Guidance Clinic of Portland, Ore., operated by the Oregon State Board of Health and the University of Oregon Medical School, where Dr. Bradley is also Associate Professor of Pediatrics and of Psychiatry.

DORIS M. HEALY, who has recently completed the five weeks' training course offered by the National Tuberculosis Association, has been appointed as trainee on the staff of the State Committee on Tuberculosis and Public Health, State Charities Aid Association, New York City.

W. C. HUEPER, M.D., has been appointed Chief of the new section of the environmental cancer section of the National Cancer Institute, U. S. Public Health Service, where he will be available as consultant to state and local health departments and industrial hygiene commissions. He was formerly Assistant Director

and Principal Pathologist of the Warner Institute for Therapeutic Research in New York City.

JAMES H. LADE, M.D.,* has been appointed Director of the Venereal Disease Control Bureau of the New York State Department of Health. Dr. Lade came to the department in 1938 as medical consultant in the Division of Syphilis Control and in 1940 was promoted to Assistant Director. He has been Acting Director since the first of 1948, and succeeds WILLIAM A. BRUMFIELD, M.D.,* recently appointed as Deputy State Health Commissioner.

ALBERT PLEYDELL recently resigned as General Manager of the Health Insurance Plan of Greater New York to join Survey Institute, management consultants on governmental and business problems, 37 Wall Street, New York, N. Y.

THOMAS ST. JOHN, M.S., a graduate of the New York School of Social Work, who has done field work with the Health Council of Greater New York, has joined the staff of the State Committee on Tuberculosis and Public Health, State Charities Aid Association, New York, N. Y., as trainee.

BRIGADIER GENERAL JAMES STEVEN SIMMONS, M.D.,* U.S.A., Retired, Dean of the Harvard School of Public Health, was elected President of the Association of Schools of Public Health at the annual meeting of the Association held at the Connaught Laboratories, University of Toronto, in April. He was awarded "The James D. Bruce Memorial Medal for Achievement in Preventive Medicine" at the Annual Convocation of the American College of Physicians in San Francisco, Calif., in April. He delivered the James D. Bruce Memorial Lecture in Preventive

* Fellow A.P.H.A.

† Member A.P.H.A.

Medicine at this meeting on the subject, "The Challenge of Preventive Medicine."

ARTHUR J. STRAWSON* retired on March 31 as Executive Secretary of the Massachusetts Tuberculosis League, Boston, Mass. He has been succeeded by C. W. KAMMEIER,† formerly Executive Secretary of the Iowa Tuberculosis Association, Des Moines.

KATHERINE Z. WHIPPLE,* Secretary of the Health Education Service of the New York Tuberculosis and Health Association, has been appointed Chairman of the Public Health Committee, Women's City Club of New York.

Southern States

NEW APPOINTMENTS TO THE U. S. PUBLIC HEALTH SERVICE, WASHINGTON, D. C.

W. PALMER DEARING, M.D.,* has been appointed Deputy Surgeon General succeeding JAMES A. CRABTREE, M.D.,* who is now head of the Medical Unit of the National Security Resources Board. In his new post, Dr. Dearing will be second in command of the Service and will act as Surgeon General in Dr. Scheele's absence. With the Service since 1934, he has been for the last 2 years Chief of the Division of Commissioned Officers. He is succeeded by EUGENE A. GILLIS, M.D.,* currently Assistant Chief of the Division of Commissioned Officers.

BRUCE D. FORSYTH, D.D.S., has become Assistant Surgeon General and Chief of the Dental Divisions, succeeding WILLIAM THOMAS WRIGHT, JR., D.D.S., who is now jointly with the Bureau of Employees Compensation, Federal Security Agency, and the Bureau of Indian Affairs, Department of the Interior.

W. THURBER FALES, M.D.,* Director of the Statistical Section in the Baltimore, Md., Health Department, was authorized by the Board of Estimates to go to Paris and Geneva at the call of the Interim Commission of the World Health Organization to participate in the International Conference for the Sixth Decennial Revision of the International Lists of Diseases, Injuries, and Causes of Death. He has also been designated a member of the United States delegation to the Paris Conference.

JOHN J. FORBES became chief of the Health and Safety Division, U. S. Bureau of Mines, Washington, D. C., on May 1, succeeding DANIEL HARRINGTON, retired. Mr. Forbes joined the Bureau of Mines as a first aid miner in 1915.

CONSTANCE LONG, R.N., has been appointed Chief of the Office of Nursing, Hospital Division, U. S. Public Health Service, succeeding JESSIE MACFARLANE, recently retired after a quarter of a century with the Service.

Western States

ADDITIONS TO COLORADO STATE HEALTH DEPARTMENT STAFF:

DOROTHY BROWN and RUTH C. COHIG as Medical Social Consultants respectively to the Tuberculosis and Maternal and Child Health Sections.

RUTH K. NESBET† as Food Sanitarian.

EUGENE A. TESELLE as Milk Sanitarian.

MARY H. EMBERTON† resigned on April 1 as Director of Public Health Nursing, Colorado State Health Department, to become Director of the Division of Visiting Nurse Service, Denver Health Department. This division is a unification of all public health

services in the city except the school nursing service.

ALFRED S. LAZARUS, PH.D.,† on July 1, became Associate Professor of Public Health and Preventive Medicine in the new School of Medicine of the University of Washington in Seattle. He will also be responsible for the establishment and operation of a laboratory for diagnostic and research work in the field of virus diseases, to cover the state. Dr. Lazarus was formerly Associate Professor of Bacteriology, University of California, Medical School, San Francisco.

Deaths

RICHARD S. AUSTIN, M.D.,† Professor of Pathology of the University of Cincinnati died April 30. He had been a member of the Coordinating Committee of the Cincinnati Public Health Federation continuously since 1932, and served as its President 1934-1937. At the time of his death he was Chairman of three important committees of the Federation, and a member of a fourth. Dr. Austin became a member of the A.P.H.A. in 1937.

SAMUEL MCCLINTOCK HAMILL, M.D.,* former President of the American Academy of Pediatrics and of the American Pediatric Society, died in Philadelphia on May 3 at age 83.

MILLARD KNOWLTON, M.D.,* who retired in 1947 after spending 23 years as Director of the Connecticut State Health Department's Bureau of Preventable Diseases, died in Hartford at the age of 73. Dr. Knowlton had been in public health work since

1911, when he directed tuberculosis prevention for the New Jersey Health Department. Later he was with the U. S. Public Health Service and the Veterans' Bureau until he was appointed to his post in the Connecticut State Health Department in 1923.

CONFERENCES AND DATES

- American Association for the Advancement of Science. Centennial Meeting. Washington, D. C. September 13-17.
- American Congress of Physical Medicine. Hotel Statler. Washington, D. C. September 7-11.
- American Dental Association. Chicago, Ill. Week of September 12.
- American Dietetic Association. Boston, Mass. October 18-22.

Relation of Economic Status to Tuberculosis Mortality by Age and Sex

MILTON TERRIS, M.D., M.P.H., F.A.P.H.A.

Medical Associate, Subcommittee on Medical Care, American Public Health Association

THE close relationship of economic status and tuberculosis mortality has been documented by numerous studies. In most of these, economic status has been defined in terms of broad occupational classes. For example, the tuberculosis mortality rates of adult males in England and Wales in 1921-1923 were found to be as shown in Table 1.¹

TABLE 1

Adjusted Mortality Rates, Respiratory Tuberculosis, Male Adults in Five Social Classes, England and Wales, 1921-1923

| Occupational Class | Mortality Rate per 100,000 |
|---------------------|----------------------------|
| I —Upper and middle | 73.2 |
| II —Intermediate | 126.3 |
| III—Skilled Labor | 146.2 |
| IV—Intermediate | 150.2 |
| V —Unskilled labor | 209.5 |

In the United States, Britten² analyzed tuberculosis mortality rates by occupational class in 10 states in 1930 as shown in Table 2.

Other studies defined economic status in terms of family income. For example, in Hamburg, Germany, in 1896-1900, the following data (Table 3) were obtained.³

TABLE 2

Adjusted Mortality Rates, Respiratory Tuberculosis, Males, 15-64 Years of Age, in 10 States, 1930, by Occupational Class

| Occupational Class | Mortality Rate per 100,000, Respiratory Tuberculosis |
|-------------------------------------|--|
| Professional men | 26.2 |
| Proprietors, managers and officials | 43.2 |
| Clerks and kindred workers | 65.8 |
| Skilled workers and foremen | 72.1 |
| Semiskilled workers | 102.1 |
| Unskilled workers | 184.9 |
| All gainfully occupied | 87.5 |
| Agricultural workers | 46.5 |

TABLE 3

Mean Annual Mortality Rates from Tuberculosis per 100,000 Persons Classified According to Family Income, Hamburg, Germany, 1896-1900

| Family Income in Marks | Tuberculosis Mortality Rate per 100,000 |
|------------------------|---|
| 900- 1,200 | 657 |
| 1,200- 2,000 | 559 |
| 2,000- 3,500 | 363 |
| 3,500- 5,000 | 228 |
| 5,000-10,000 | 183 |
| 10,000-25,000 | 172 |
| 25,000-50,000 | 221 |

In the United States, Chapin found that in Providence, R. I., in 1865, the adjusted mortality rate from pulmonary tuberculosis among the 10,515 income

taxpayers was 139.7, as compared with a rate of 431.0 among the 44,080 non-taxpayers.⁴

Green determined tuberculosis mortality rates in the census tracts of the Cleveland Five-City Area in 1928-1931, using equivalent monthly rentals as the measure of economic status, with results shown in Table 4.⁵

TABLE 4

Adjusted Tuberculosis Mortality Rates, White Population, Cleveland Five-City Area, 1928-1931, by Economic Area

| Economic Area | Tuberculosis Mortality Rate per 100,000 (White) |
|---------------|---|
| 1} Lowest | 127 |
| 2} | |
| 3 | 78 |
| 4 | 74 |
| 5 | 55 |
| 6 | 48 |
| 7 | 45 |
| 8 | 34 |
| 9 | 29 |
| 10 | 26 |
| 11 | 27 |
| 12 | 22 |
| 13} Highest | 19 |
| 14} | |

One of the findings of the National Health Survey made in 1935-1936 was a well defined relationship between economic status and disability from tuberculosis (Table 5).⁶

As a result of these and similar studies it has become an accepted fact that occupational class and economic status bear a definite relationship to tuberculosis mortality as well as disability. Unfortunately there has been little disposition to probe further to determine which factor or factors in economic

TABLE 5

Days of Disability per Person per Year from Tuberculosis, for Persons of All Ages, According to Economic Status

| Annual Family Income or Relief Status | Days of Disability from Tuberculosis per Person per Year |
|---------------------------------------|--|
| Relief | 0.70 |
| Non-relief | |
| Under \$1,000 | 0.31 |
| \$1,000-\$1,500 | 0.20 |
| \$1,500-\$2,000 | 0.14 |
| \$2,000-\$3,000 | 0.11 |
| \$3,000 and over | 0.08 |

status or occupational class are responsible for the relationship.

It is clear that several causes may be involved—overcrowding, bad housing, poor nutrition, overwork, increased exposure to infection, etc. It is extremely difficult to separate these factors, since the groups which have a low economic status generally tend to be unskilled laborers who have strenuous jobs and suffer from overcrowding, poor housing, and malnutrition. How then can a more refined analysis be obtained?

One method is to compare urban and rural populations which have a similar status in terms of family income. The author is not familiar with any such study. However, the fact, that Britten found the tuberculosis mortality rate to be only 46.5 among agricultural workers as compared with 87.5 among all gainfully occupied persons (Table 2) would tend to indicate that economic status *per se* is not the only determinant and that other factors related to urban living probably play a significant role.

Another method which may be used

TABLE 6

Tuberculosis Mortality Rates by Age and Sex per 1,000 Persons in Copenhagen, Denmark, According to Broad Occupational Classes, 1865-1874

| Occupational Class | All Ages 20 & over Adjusted | 20-24 | 25-34 | 35-44 | 45-54 | 55-64 | 65 and over |
|---|-----------------------------|-------|-------|-------|-------|-------|-------------|
| Males | | | | | | | |
| Professional, Salaried and Merchant Class | 3.4 | 3.4 | 3.3 | 3.1 | 3.4 | 4.4 | 2.9 |
| Working Class | 6.9 | 4.3 | 4.5 | 6.0 | 8.8 | 13.3 | 10.6 |
| Females | | | | | | | |
| Professional, Salaried and Merchant Class | 2.4 | 2.6 | 2.7 | 2.4 | 2.2 | 2.2 | 1.3 |
| Working Class | 3.4 | 1.9 | 2.6 | 4.0 | 4.4 | 4.5 | 4.5 |

is to compare the tuberculosis mortality of males and females in various economic classes. Data in Table 6 were obtained for Copenhagen, Denmark, for the years 1865-1874.⁷

It will be noted that among adult males, the tuberculosis mortality rate is twice as high in the working class as in the professional, salaried, and merchant class. Among adult females, however, the difference is not as marked; the rate in the working class is only $1\frac{1}{2}$ times as high as in the other classes.

Green⁸ studied the age- and sex-specific tuberculosis mortality rates in Cleveland in 1928-1931 for two contrasting economic areas—the Low Area, which consisted of a population of approximately 100,000 living in census tracts having the lowest equivalent monthly rentals, and the High Area, consisting of a population of about 100,000 living in census tracts having the highest rentals. He found that in the Low Area the male rate was quite similar to the female rate up to age 25, after which the male rate was very markedly greater. In the High Area, on the other hand, the male and female rates were found to be quite similar throughout, both being much lower at all ages than was found to be the case in the Low Area.

Sydenstricker⁹ compared age-specific tuberculosis mortality rates among males and females in urban and rural areas in nine states in 1908-1912 and among insured members of wage earners' families in 1911-1916. He found that although there were some differences in the rates for adult females in the rural, urban, and insured wage earners' families (highest in the wage earners' families), these differences were fairly small. Among adult males, however, there were very striking differences, with the rural rates considerably below the urban and these in turn considerably lower than the rates among insured wage earners. He concluded that: "The rate for adult

wage earning males, especially in middle age after they have been at work a number of years, is in excess of that for any other group. The possibility that 'race' or, to put it more exactly, country of birth—*per se* was an important factor may be dismissed since females were largely of the same nationality as their husbands at the time covered by the statistics used. Yet wives, living in the same economic, social, and home environment, did not die from the disease to nearly the extent that their wage earning husbands did. . . . It is not 'conditions of life' only, but also the particular conditions constituting occupational environment, which are responsible for the greater mortality rate among male wage earners in the prime of life in cities than among women in general or among men in other pursuits."

The present study of tuberculosis mortality in the city of Buffalo gives striking confirmation of Sydenstricker's findings. Buffalo is an important industrial center, with large steel, auto, railroad, grain, aircraft and electrical industries. Its population in 1940 was 575,901, of which 81 per cent were native white, 16 per cent foreign-born white, and 3 per cent non-white, mainly Negroes.

The 1940 Census data on population and socio-economic characteristics of the 72 census tracts in Buffalo were used. The relative economic status of the population in each census tract was determined by combining four indices: median monthly rent, proportion of homes with central heating, proportion of homes with mechanical refrigeration, and median years of school completed. Statistical analyses made by the Buffalo Foundation have demonstrated that these factors are closely correlated, and that consideration of all four factors yields a more reliable measurement of average income and economic conditions than the use of a single factor.

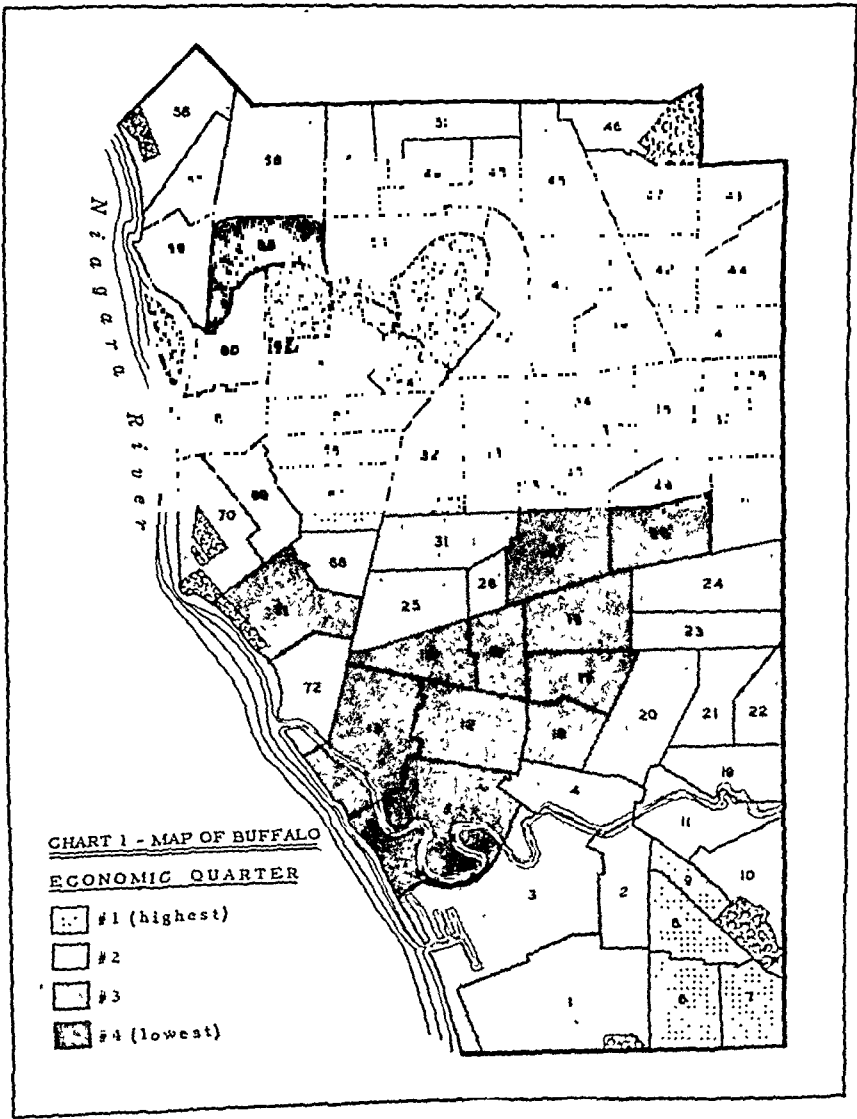

The city was grouped into four quar-

ters of approximately 145,000 population each on the basis of economic status. The classification of census tracts into the four economic quarters is shown on the map, Chart 1. Resident tuberculosis deaths occurring during the three year period 1939-1941 were used to determine annual tuberculosis death rates by age, sex, and color for each of the four quarters as well as the city as a whole.

Tuberculosis mortality by age, sex, and color for the City of Buffalo is shown in Table 7 and Chart 2. It will

be noted that there is a significantly higher male death rate after the third decade for both the white and non-white populations (the non-white population in Buffalo is almost entirely Negro). This finding is essentially consistent with the data obtained for all cities of over 100,000 population in the United States.¹⁰

Tuberculosis mortality rates by age and sex were calculated for the white population in each of the economic quarters. Similar comparisons for the non-white population could not be made

CHART 2 - Tuberculosis Mortality Rates by Age, Sex and Color - Buffalo, 1939-41

| 65 and over | 216 | 0 | 0 | 250 | 0 | 0 |
| Total | 9,134 | 78 | 284.6 | 9,149 | 52 | 189.4 |
| <i>Total</i> | | | | | | |
| Under 5 | 18,871 | 7 | 12.4 | 18,465 | 16 | 28.9 |
| 5-14 | 43,079 | 6 | 4.6 | 42,978 | 12 | 9.3 |
| 15-24 | 49,765 | 45 | 30.1 | 53,021 | 83 | 52.2 |
| 25-34 | 46,048 | 62 | 44.9 | 48,891 | 77 | 52.5 |
| 35-44 | 43,343 | 126 | 96.9 | 44,452 | 52 | 39.0 |
| 45-54 | 41,150 | 162 | 131.2 | 38,927 | 34 | 29.1 |
| 55-64 | 24,655 | 101 | 136.6 | 24,699 | 25 | 33.7 |
| 65 and over | 16,856 | 46 | 91.0 | 20,701 | 23 | 37.0 |
| Total | 283,767 | 555 | 65.2 | 292,134 | 322 | 36.7 |

because the non-white population in the two highest quarters is negligible. The results are shown in Tables 8 and 9 and Charts 3 and 4. It is seen that before the third decade there is some difference in tuberculosis mortality by eco-

nomie status for both sexes. After the third decade, however, there is a very large difference in mortality among the males of the various economic groups, while there is only a moderate difference in mortality among females.

CHART 3 - Tuberculosis Mortality Rates, White Males, by Economic Quarter - Buffalo, 1939-41

CHART 4 - Tuberculosis Mortality Rates, White Females, by Economic Quarter - Buffalo, 1939-41

TABLE 10
*Adjusted Tuberculosis Mortality Rates of White Population by Sex, Major Age Groups,
 and Economic Status, Buffalo, 1939-1941*

| Sex and Economic Status | Adjusted Tuberculosis Mortality Rates | | |
|------------------------------|---------------------------------------|-------------------|-------|
| | Under 35 years | 35 years and over | Total |
| Males | | | |
| Economic Quarter 1 (highest) | 17.3 | 46.7 | 30.3 |
| 2 | 17.0 | 80.9 | 45.4 |
| 3 | 16.3 | 125.9 | 64.9 |
| 4 (lowest) | 31.1 | 172.4 | 93.8 |
| Females | | | |
| Economic Quarter 1 (highest) | 23.9 | 20.8 | 22.6 |
| 2 | 32.3 | 25.2 | 29.2 |
| 3 | 25.8 | 41.5 | 32.7 |
| 4 (lowest) | 46.2 | 45.3 | 45.8 |

The magnitude of these differences is indicated in Table 10, which gives the tuberculosis death rates below and above age 35, adjusted to the entire population of Buffalo as the standard population. It will be noted that below age 35, the tuberculosis mortality for both males and females in the lowest economic quarter is about double that in the highest quarter. Likewise, in females age 35 and over, the mortality in the lowest economic quarter is a little more than double that in the highest quarter. But for males age 35 and over, the mortality in the lowest economic quarter is almost four times as great as in the highest quarter.

The difference in tuberculosis mortality between the highest and lowest economic quarters is statistically significant* for all groups, i.e., for males 35 years and over, females 35 and over, males below 35, and females below 35. However, only in males 35 years and over are all the differences in mortality between each economic quarter and the next highest economic quarter statistically significant. It is fair to conclude, therefore, that the differences in mortality for males 35 years and over among the different economic groups are significantly greater than for females in the same age classification.

These data indicate that the high male mortality after age 35 is not merely a matter of economic status *per se*. If it were, the females in the lower economic groups should show a similar rise in mortality after age 35. It is reasonable to assume, therefore, that other factors associated with economic status, but more or less limited to males, are responsible for the differences found in the four economic groups of males after age 35.

The most striking difference in the mode of life of adult men and women relates to occupational status. In Buffalo in 1940, 62 per cent of the 226,704 males age 14 years and over were employed, while of the 235,587 females age 14 and over, only 23 per cent were employed and 55 per cent were engaged in housework in their own homes. Also, Table 11 shows that in 1940, 57 per cent of the employed males in the highest economic quarter in Buffalo were professional workers; semi-professional workers; proprietors, managers, and officials; and clerical, sales and kindred workers. Only 18 per cent of the employed males in the lowest quarter were in these categories. On the other hand, 50 per cent of the employed males in the lowest economic quarter were classified in the 1940 census as operatives and laborers, as compared with only 17 per cent in the highest quarter.

There are several factors associated

* A difference of two or more standard deviations was considered statistically significant.

*Occupational Status of Employed Males in Each of the Four Economic Quarters, Buffalo 1940 (U. S. Census) **

| <i>Economic Quarter</i> | <i>Per cent of Total</i> | |
|-------------------------|---|--------------------------------|
| | <i>Professional; Semi-Professional; Proprietors, Managers, and Officials; Clerical, Sales and Kindred Workers</i> | <i>Operatives and Laborers</i> |
| 1 (highest) | 57.3 | 16.9 |
| 2 | 32.4 | 31.7 |
| 3 | 26.3 | 38.6 |
| 4 (lowest) | 18.4 | 49.5 |

* Includes both whites and non-whites. Data not available for whites only.

with occupation which might be considered to contribute to the differences found. It might be postulated, for example, that the higher tuberculosis mortality among adult men in the low income groups is due to their position as family breadwinners who are therefore more likely to postpone needed hospitalization than are women in the same strata. While this explanation appears reasonable, some doubt is cast on its validity by the fact that Sydenstricker discovered the phenomenon of disproportionately high tuberculosis mortality among adult wage earning males in 1911-1916, when the sanatorium movement was in its infancy and hospitalization for tuberculosis could not therefore be expected to play a significant role in reducing mortality.

It is conceivable that silicosis may play some part in the differences found. While industry in Buffalo is for the most part apparently not of the character associated with silicosis, there is no definite information at this time concerning the extent of the hazard and the actual incidence of silicosis in the area.

It is also possible that there are larger differences in extra-familial exposure to tuberculosis among males in the four economic groups than among females. This factor may play a definite role but is somewhat difficult to evaluate.

A major consideration which may help explain the findings relates to the adverse effects of overexertion on patients with tuberculosis. Physical overstrain

is characteristic of the tasks of the unskilled laborers who make up 50 per cent of the employed males in the lowest economic quarter of Buffalo and only 17 per cent of employed males in the highest quarter. The importance of overexertion in the prognosis of tuberculosis has long been recognized; it forms the basis for our therapeutic approach to the disease; and in recent years has influenced greatly our thinking with respect to rehabilitation. It has become very clear that a recovered tuberculosis patient cannot be returned to an occupation requiring strenuous physical exertion without running serious risks of early breakdown and recurrence. The result has been an emphasis on retraining patients for occupations requiring less physical exertion and on the development of sheltered workshops. It would appear logical therefore to suggest that physical overstrain plays an important role in the disproportionately high tuberculosis mortality among adult males in the lower income groups.

It must be recognized however that this brief discussion of possible explanations for the high tuberculosis mortality of low-income adult males is on a speculative level. The conditions of the study did not permit isolation of the individual factors in order to determine their relative influence.

SUMMARY AND CONCLUSIONS

1. Numerous studies have shown the

close correlation of occupational class and economic status with tuberculosis mortality and disability.

2. Analysis of tuberculosis mortality by age, sex, and economic status in Buffalo, 1939-1941, indicates that the inverse correlation of economic status with tuberculosis mortality is greater for adult males than for adult females.

3. It is concluded therefore that economic status *per se* is not the only factor involved, but that conditions of occupation probably have an important effect. Various aspects of occupational environment are discussed, and it is suggested that the factor of physical overstrain plays a significant role.

4. It is recommended that similar studies be conducted in other cities to test the general validity of the findings, and that further studies be instituted to isolate the various factors, if possible,

in order to determine their relative influence on tuberculosis mortality.

Rheumatic Heart Disease and Crowding

A Survey of Rural and Urban Connecticut School Children

ROBERT W. QUINN, M.D.*

WITH THE ASSISTANCE OF

JOHN H. WATKINS, PH.D., AND JULIA P. QUINN, M.S.S.

*Section of Preventive Medicine, Yale University School of Medicine,
New Haven, Conn.*

ATTEMPTS have been made for over 50 years to relate the prevalence of rheumatic fever and rheumatic heart disease to climate and special types of living conditions. From an epidemiological standpoint these two environmental influences are closely associated, in that temperature, rainfall, and altitude, or so-called macro-climate,[†] are important factors in influencing the extent to which people spend their time indoors, and these in turn influence crowding and spread of droplet infection. On the other hand, the living conditions in which we are interested here refer to the immediate surroundings of the individual, whether urban or rural, the environment within his home including dampness, crowding, food, and clothing.

The previous studies which have attempted to relate urban living conditions with the prevalence of rheumatic fever are many and variable. They include those of Perry and Roberts in Bristol,

England,² the British Medical Association in England,³ Hedley in Philadelphia,⁴ Clark in Dublin, Ireland,⁵ Maddox in New South Wales, Australia,⁶ and many others. Some of these studies have been summarized in a review on the general subject of the Epidemiology of Rheumatic Fever which appeared in 1943.⁷ The conclusions to be drawn from the summary of the literature at that time, which covered a series of observations made over a period of perhaps 60 years, were, that along with other factors, environmental or living conditions do play a part in determining the prevalence of rheumatic fever. Thus, evidence has been cited which supports the view that the prevalence of rheumatic fever is higher in low income areas than in areas occupied by higher income groups and in urban than rural areas. It has also been thought that damp living quarters seem to furnish opportunity for the spread of the disease, but this observation has not been corroborated by all who have attempted to evaluate its importance. Dietary deficiencies likewise have been considered by some as a predisposing factor in this disease. Since 1943 there have been a few new observations on this subject, notably those of the Wedums.⁸ Their study again emphasized the importance of low income and crowding in the genesis of rheumatic fever. In general then,

* Milbank Memorial Fund Fellow, 1946-1947.

Aided by a grant from the Life Insurance Medical Research Fund.

† The terms macro-climate and micro-climate have been used to designate "epidemiological climates" by Poynton,¹ and have been attributed by him to Danilevsky of Moscow. According to their interpretations macro-climate is climate in the ordinary meteorological sense—temperature, rainfall, and altitude, whereas micro-climate is the sum of the intimate sociological and domiciliary conditions wherein a given individual finds himself or herself.

it has been thought that crowded urban living conditions do represent the best setting in which rheumatic fever and streptococcosis may flourish.* In accepting this view, however, it would seem that actually none of the studies reported so far have proved conclusively the importance of crowding within an urban environment.

In the present study an attempt has been made to meet this objection and to carry out observations which would be acceptable from a biostatistical point of view. The purpose has been to select and examine comparable rural and urban populations from a single small area of the United States and to determine as accurately as possible the rates for rheumatic heart disease in each population. The primary assumption was that within this small area (the State of Connecticut), the variations of climate and altitude are not large enough to be significant, and so an answer to the first question can be properly sought; namely, can one demonstrate significant differences in the prevalence of rheumatic heart disease between these two groups of children, one rural and the other urban, exposed to the same macroclimate but different micro-climates. Other questions to be answered are: what is the effect of living conditions within high and low rental areas in cities, and what effect does crowding in the home have on the prevalence of rheumatic heart disease. And finally,

what is the familial incidence of rheumatic fever and rheumatic heart disease in this geographical area?

METHODS

Previous surveys on the prevalence of rheumatic heart disease in school children have employed methods which were comparable to those used in this study. They include those of Paul, *et al.*,¹⁰ Paul and Dixon,¹¹ Paul and Deutsch,¹² the Wedums,⁸ Sampson, *et al.*,¹³ and Quinn.¹⁴

A. *Geographical area or locale*—The survey was confined to the geographical limits of the State of Connecticut.

B. *Selection of age group to be examined*—Children of both sexes in the 7th and 8th grades of Connecticut Public Schools only were included in the study. Their ages range from 11 through 15, with the average around 13. This seemed to be an optimal age group for this study because the children already had passed the age at which rheumatic fever usually is acquired (7–10 years) and there had been an interval period during which they might develop recognizable rheumatic heart disease.

C. *Methods for selecting schools*—The original plan was to select and examine 1,000 rural and 1,000 urban school children. Eventually a somewhat larger group was selected. The representative sample of rural children was chosen from widely scattered areas throughout the state. Urban children were selected from the cities of Ansonia, Bridgeport, Hartford, and Waterbury. An effort was made to select adequate samples from the low, medium, and high rental areas of these cities. (For a complete description of these methods see the appendix.)

D. *Organization*—As soon as the individual schools had been selected, letters explaining the survey and asking permission to carry out the study were sent to the school superintendent, the school health officer (or city health de-

* In this study it is recognized from the outset that the concept of rheumatic fever as a separate and specific clinical entity is no longer tenable, for such a close relationship has been established between rheumatic fever and infections of the upper respiratory tract due to the hemolytic streptococcus, that it is now obvious that the epidemiology and pathogenesis of both diseases are closely related. The general relationships between streptococcal infections of the upper respiratory tract and rheumatic fever will not be considered in this study. It will be assumed nevertheless, that rheumatic fever is one of the manifestations of streptococcosis,⁹ and that indefinite as the diagnosis of rheumatic fever may be, it can be discussed as a clinical entity. Rheumatic heart disease, however, is a rather distinct clinical manifestation of the disease called rheumatic fever, and its prevalence can be measured.

partment in some schools without school physicians), the school nurse and principal. These letters were followed by a visit from the survey physician and social worker to explain further the purpose of the survey and make arrangements for the examination place and date.

Permission blanks for the patient's signature were given to the school nurse for distribution. No child was examined without the permission of the parents. Coöperation between the nurses, teachers, principals, superintendents, and physicians proved to be excellent.

E. *Examinations*—At the appointed time examinations were carried out in the most suitable place. In some country schools, a section of the room was screened off and desks were pushed together to serve as an examining table. Whenever possible, the school nurse aided in the examination. When there was no school nurse, the social worker (J.P.Q.) performed the nurse's duties. Parents were invited to attend the examinations but did so in a small (less than 5) per cent of the examinations.

Medical and social histories were taken by the social worker (J.P.Q.) and the medical history was taken in more detail by the physician in all cases of cardiac suspects, and in those who gave a history of previous rheumatic fever, chorea, or any illness resembling rheumatic fever. After the history taking, the child was examined. Screens were used to insure privacy, and gowns were furnished for the girls. The examination was confined to the cardiovascular system. All examinations were carried out by the same physician. (R.Q.)

F. *Determination of statistical significance*—(Methods of selection of schools and statistical analyses were supervised by J.H.W.) The chi-square test¹⁵ was used throughout, to determine the statistical significance of the observed rates for rheumatic heart dis-

ease, potential heart disease, etc. The value of P, the probability corresponding to the computed chi-square was determined from a graph devised by the Department of Pharmacology, Yale University. Values of chi-square corresponding to a probability of 0.05 or less were considered as indicating significant deviations from expectation.

G. *Reporting of cases*—All cases of rheumatic heart disease, possible heart disease, congenital heart disease, and possible congenital heart disease, as well as children with a past history of rheumatic fever were reported to the Division of Crippled Children of the Department of Health of the State of Connecticut. About half of the cases of rheumatic heart disease had not been recognized previously. In this manner the study served as a valuable case finding measure.

CRITERIA

A. *Diagnostic Criteria*—The criteria which were used to establish a diagnosis of rheumatic heart disease, unexplained murmurs, rheumatic fever, possible heart disease, and congenital heart disease are described below. These diagnoses were based on single clinical observations almost entirely, in that supplementary roentgenographic and electrocardiographic examinations were not done. An attempt was made to estimate the heart size of each child by measuring the point of maximum impulse and the relative cardiac dullness.

Mitral insufficiency—This diagnosis was made in the presence of a relatively high-pitched, moderately loud to very loud, systolic, apical murmur beginning early in systole immediately after the first heart sound and transmitted to the left axilla.

Mitral stenosis was considered to be present when a low-pitched, rumbling, soft, to moderately loud, diastolic apical murmur with or without presystolic accentuation was heard. The second

sound in the pulmonic area was accentuated.

Aortic insufficiency was indicated by a rather soft, high-pitched, blowing, diastolic murmur heard best along the left sternal border or over the sternum in the 3rd and 4th left interspaces. This murmur was heard best with the patient's breath held in expiration and the patient bent forward while in the sitting position. Increased pulse pressure, a collapsing (Corrigan) pulse, capillary pulsation, and pistol shot sounds over the femoral arteries were not always present, but helped to establish the diagnosis when they were present.

Unexplained or so-called functional murmurs were nearly always systolic in time. They were soft to moderately loud, heard most frequently at the base of the precordium in the pulmonic area, next most frequently medial to the apex, and least frequently along the left sternal border. The murmurs were well localized and only slightly accentuated by exercise or change of posture.

History of rheumatic fever—Children who gave a reasonably clear past history of rheumatic fever or chorea were classified under the heading of "History of Rheumatic Fever." It was not often possible to corroborate the accuracy of these histories by interviewing the child's parents or physician and therefore the degree of accuracy of this classification is probably not high.

Family history of rheumatic fever—A positive family history of rheumatic fever was recorded when there was a reasonably good story of rheumatic fever, chorea, or rheumatic heart disease in any of the child's parents, siblings, aunts, uncles, or cousins.

Congenital heart disease—It is often impossible to establish a correct anatomical diagnosis in congenital heart disease on the basis of physical findings alone; however, when the physical signs of congenital heart disease were clear-cut, the diagnosis was made.

Possible heart disease—Certain cases have been classified as either possible congenital heart disease or possible rheumatic heart disease, depending on the physical findings.

B. Criteria for crowding within homes—The degree of crowding was determined on the basis of number of persons per room within each child's home. Crowding was designated as existing in urban homes when there was less than one room per person; and in rural homes when the number of rooms was two less than the number of occupants. The decision to make this differentiation between crowding in rural and urban homes was reached after interviewing the children, school nurses, and teachers, as well as personal observation of many of the rural homes. It was evident that a family of nine living in a large eight room farm house was not crowded. Actually crowding is difficult to estimate and it is evident that both rural and urban children are exposed to crowding in varying degrees in their homes and sleeping quarters as well as elsewhere. Crowding in rural homes was probably more frequent than the figures indicate since it was observed that many rural families closed off part of their homes during winter months and lived in the few heated rooms: this practice makes for crowding regardless of the number of rooms in the home. It was also observed that the rural child is exposed to crowding when he rides in school buses or attends a one-room school house which is poorly ventilated in winter months. Many rural children attended consolidated schools which were similar to urban schools in ventilation and number of students per room. The urban child regardless of the rental area in which he lives is exposed to crowding in the schools, theaters, public conveyances, and school buses.

Race—All the children were either white or Negro except in a single instance of a Chinese child. No attempt

was made to classify them according to nationality groups.

RESULTS

The survey was begun in the first week of October, 1946, and completed during the second week of June, 1947. The survey team (R.Q. and J.P.Q.) travelled approximately 10,000 miles. Thirty-one hundred and forty-one children in the 7th and 8th grades were interviewed and examined—of this number 1,092 were rural school children, 138 semi-rural, and 1,911 urban.

General Rates—A general compilation of data relating to the three groups of children (rural, semi-rural, and urban) appears in Table 1. From this table it appears that the rheumatic heart disease rates are 1.6, 1.4, and 2.5 per cent respectively, and it would seem that the prevalence of both rheumatic heart disease (2.5 per cent) and possible rheumatic heart disease (4.3 per cent) is higher in the urban than the rural group of children, but when the chi-square test was applied, these differences were not statistically significant.

Urban Rates—An attempt was made to analyze further the results of the examinations of the urban children from the cities of Bridgeport, Hartford, Waterbury, and Ansonia. In the first three cities the rheumatic heart disease rates (average of 3 cities 2.13 per cent) did

not differ significantly; but a significantly higher rate was found in Ansonia (5.02 per cent). These data, shown in Table 2 will be discussed later. For

this analysis the urban children were classified into three groups, namely, those living in low, medium, and high rental areas (Table 3). The rheumatic heart disease rates in these rental areas were 2.5, 2.7, and 1.4 per cent respectively, but the differences were not statistically significant. In reference to this table, it should be pointed out that the degree of crowding increased markedly from the high rental areas to the low rental sections. The observed incidence of rheumatic heart disease and possible rheumatic heart disease and family history of rheumatic heart disease tends to be higher in the low rental

TABLE 4

Observed Number and Per cent of Rheumatic Children Living in Crowded and Non-crowded Urban and Rural Homes

significant

areas, as opposed to the high rental group, but here again when these differences are analyzed statistically, the variations are not significant.

Crowding—In Table 4 is shown the effect of crowding on the number and per cent of rheumatic children. The number of rheumatic children living in crowded homes, regardless of the rural or urban location of the home, was significantly higher than the number in non-crowded homes.

The percentage of children with unexplained murmurs (approximately 30 per cent) was similar among the rural, semi-rural, and urban groups of children.

The relatively small number of 18 children with congenital heart disease is in keeping with general pediatric experience—rheumatic heart disease being by far the most common type of heart disease in children above the age of 5 years.

| Total | | | |
| Observed number | 42 | 25 | 67 |
| Per cent of Total Number with R.H.D. | (62.7) | (37.3) | (100) |

Among the 147 children with a positive family history of rheumatic fever, 12.9 per cent had a personal history of rheumatic fever or had evidence of rheumatic heart disease, as compared with 3.8 per cent among children with a negative familial history of rheumatic fever or rheumatic heart disease. This highly significant difference has been demonstrated by others many times.

The anatomical diagnoses of the cases of rheumatic heart disease are recorded in Table 5. Mitral insufficiency was by far the most common form of rheumatic heart disease. The difference between the per cent of males and females with rheumatic heart disease was not statistically significant.

DISCUSSION

The results of this study would indicate that rheumatic fever and rheumatic heart disease are common and widespread among Connecticut school children. One and six-tenths per cent represents a close approximation to the true rheumatic heart disease rate for rural Connecticut School Children in the 7th and 8th grades within the confidence limits of 0.89 and 2.39. All that can be said of the urban rheumatic heart disease rate of 2.5 per cent is that it is the rate for a sample of children taken from the four cities of Ansonia, Bridgeport, Hartford, and Waterbury. The failure to find significant differences between the rheumatic heart disease rates

for rural (1.6 per cent) and urban children (2.5 per cent), between the rates for children living in the low (2.5 per cent), medium (2.7 per cent), or high (1.4 per cent) urban rental areas, or even between the rates for rural children (1.6 per cent) and urban low rental area children (2.5 per cent) would suggest that the epidemiological factors which control the prevalence of rheumatic fever are today (in 1946-1947) common to both rural and urban Connecticut as well as to different rental areas in the four cities studied. These findings in general do not support the usual concept that the prevalence of rheumatic fever is highest in congested, low income urban areas. However, it should be pointed out that a larger number of observations might have made the observed differences statistically significant.

As shown in Table 2, the rheumatic heart disease rate for Ansonia, one of the cities chosen for study (5.02 per cent), was considerably higher than the observed rates for the other three cities (2.13 per cent). A similar high rate for Ansonia was found in a previous survey in 1940.¹² The reasons for this difference are not clear. It cannot be attributed to a higher familial incidence of rheumatic fever or a higher degree of crowding among the children examined, or a higher rheumatic fever rate in the Ansonia group of children, because the observed incidence of family history of rheumatic fever, crowding, and past history of rheumatic fever in the Ansonia group were not significantly different from the rates observed in the three larger cities.

Although this study was not designed to investigate all possible epidemiological factors in rheumatic fever and rheumatic heart disease in Connecticut, certain observations on the effect of crowding on these rates were made, and here, in contrast to the fact that differences in rheumatic heart disease rates between

urban versus rural environments, and between high and low rental areas are not significant, the effect of crowding within the home does appear to be significant. The data in Table 4 indicate that the number of rheumatic children (children with rheumatic heart disease or a history of rheumatic fever) living in crowded homes is significantly higher than the number of rheumatic children living in non-crowded homes, regardless of the rural or urban locations of the home. These observations suggest that for rheumatic children the risk of contracting rheumatic fever was just as great in a crowded rural home as in a crowded urban home. On the other hand, crowding in the home was over three times as common in urban as in rural and semi-rural homes; in low rental area urban homes, crowding was twice as frequent as in medium rental area homes, and six times as common as in high rental area homes; yet there was no significant difference in the rheumatic heart disease rates for children living in any of these areas.

How can these differences be interpreted? The data do support the idea that crowding within the home is related to an increased prevalence of rheumatic heart disease, and that environmental influences are important in determining its presence. These findings are in keeping with those of Perry and Roberts.² Whether environmental, social, and economic conditions have changed, or for other reasons, these data do not support the statement based on data collected some 30 years ago that rheumatic fever is 30 times as common in industrial as in rural towns.¹⁰ Today, outside the home, the micro-climate in which a child lives is apparently much the same for all children, regardless of the rural or urban area in which they live. In this observation lies a possible explanation of the previously mentioned differences.

SUMMARY AND CONCLUSIONS

1. The results of a rheumatic heart disease survey of a sample of rural, semi-rural, and urban Connecticut school children have been presented in which analyses were made for rates in urban versus rural areas, urban low rental areas versus high rental areas, and crowding versus absence of crowding.

2. The rheumatic heart disease rate for the sample of rural children examined was 1.6 per cent, for semi-rural children 1.4 per cent, and for the sample

of urban children living in the Connecticut cities of Ansonia, Bridgeport, Hartford, and Waterbury, it was 2.45 per cent. The differences between the rural, semi-rural, and urban rates are not statistically significant.

3. The rheumatic heart disease rate for children in one city—Ansonia—of 5.02 per cent was significantly higher than the rural rate or combined rate found in Bridgeport, Hartford, and Waterbury. The reasons for these differences are not known, but they are in

keeping with previously expressed ideas that this disease does flourish more in certain localized places than in others.

4. The rheumatic heart disease rate for urban children living in low rental areas was 2.5 per cent, in medium rental areas 2.7 per cent, and in high rental areas it was 1.4 per cent. These differences were not statistically significant and, furthermore, there was no significant difference between the rheumatic heart disease rate for low rental area urban children and the similar rate for rural children.

5. One feature which did stand out was the effect of crowding within the home which was apparently an important factor influencing the prevalence of rheumatic heart disease; the rate in crowded homes being almost twice that in non-crowded homes.

6. The other findings of the survey failed to show significant differences, with the exception of familial history of rheumatic fever or rheumatic heart disease which was significantly higher among rheumatic children.

APPENDIX

1. Selection of sample of rural children—

In estimating the size of the sample needed to make the study statistically valid, the following conclusions were drawn:

a. If 1,000 rural children were examined and the incidence of rheumatic heart disease was somewhere about 1.3 per cent (the rate from a previous rheumatic heart disease survey in rural Connecticut school children), then the true value in the population would be between 0.6 and 2.0 at the confidence level of 0.05.

b. For the true population value to be within 10 per cent of 1.3 per cent, 29,000 observations would be needed at the same confidence level.

c. For the true population value to be within 100 per cent of 1.3 per cent, i.e., 0 to 2.6, 290 observations would be needed at the same confidence level.

Because of time and personnel limitations, it was decided to limit the sample of rural children to about 1,000. Actually, 1,092 rural children were examined, and 18 were found to have rheumatic heart disease (1.64 per

cent). The confidence limits were calculated as 0.89 and 2.39 by the usual method.¹⁵

2. In order to secure a representative cross-section of the rural population, stratification by geographical areas throughout the state by counties was done. The towns and schools selected, and the number examined in each school are shown in Table 6.

Accordingly selection of 81 minor divisions within the 8 Connecticut counties was made on the basis of "rurality" judged from the U. S. Census figures for 1940.¹⁷ In the towns selected over 25 per cent of the population were engaged in farming, and many more families were living in the country although not actually engaged in farming. No towns with over 0.18 persons per acre were selected.

3. Selection of a representative cross-section of the rural population within each county—

a. Determination of the number to be drawn from each county:

(1) Rural towns were classified by counties.

(2) The rural school population in each county was determined from data furnished by the State Board of Education.

(3) These numbers of children were expressed in percentages of the total rural population of the state.

(4) The total sample size (1,000) was then multiplied by those percentages to give the sample needed from each county.

b. Cluster sampling within each county was then carried out:

(1) The number of rural schools in each county was obtained.

(2) The 7th and 8th grade population in these schools was secured from local school superintendents.

(3) To obtain the average number of 7th and 8th grade pupils in each school in the county b(2) was divided by b(1).

(4) To determine the number of schools necessary to select, the sample size a(4) was divided by b(3).

(5) Selection of specific schools was done by random sampling, e.g., if 9 schools were necessary out of 34 schools—these schools were selected by use of random numbers.

c. Selection of sample of urban children.

Three of Connecticut's largest cities—Hartford, Waterbury, and Bridgeport—plus one smaller city, Ansonia, were chosen. An attempt was made to select schools within these cities which were representative of low, medium, and high rental areas. An arbitrary

division was made on the basis of average monthly rentals of \$0-\$29 for the low rental areas, \$30-\$69 for the medium group, and \$70 and over for the high rental group. This division into three rental areas was used as a rough guide to relative family income, housing, food and clothing budget, etc. Average monthly rentals were determined from Housing Analytical Maps.¹⁸ In addition, following examination, each child was located in the correct rental area by his address. This was accomplished through the combined use of the Housing Analytical Map and the city street guide and map. This was not possible for Ansonia where a housing map or city street guide was not available. In this city children were placed in the correct rental area by data furnished by the school nurse supplemented by personal observation of each child's home by the social worker.

"The challenge of today's crisis is the most commanding which Western society has ever faced. We have always known that knowledge was a perilous possession, because it could equally well work in the wrong direction; but the knowledge that has been placed in the hands of this age is so supremely capable of misuse—and misuse could so easily reduce the hopes and monuments of men to drifting dust—that the impact of the challenge finds us confused, uncertain and fearful.

"Like all frightened people every-

where and in all ages, our first reaction is physical force, and our instinctive faith is given to military power. Let us grant at once that in this unprecedented crisis a measure of physical force is essential. We do not live in a utopia, and it would be suicidal to act as if we did. Equally suicidal, however, is the assumption that the crisis can be met solely on the level of force, or that mechanisms, power and dollars constitute the essential elements of the solution."—Raymond B. Fosdick, *Rockefeller Foundation—A Review for 1947*.

The Rheumatic Fever Community Program

Its Value in the Epidemiological Study of Rheumatic Fever

SUMMARY OF THE SYMPOSIUM * PREPARED BY THE MODERATOR

DAVID D. RUTSTEIN, M.D., F.A.P.H.A.

AT THE Annual Meeting of the American Public Health Association in Cleveland, Ohio, November 13, 1946, a symposium on the organization of community rheumatic fever programs was conducted.† At that time it was pointed out that such a program would bring many benefits to a community. These include: (1) facilities for the precise diagnosis of rheumatic fever, which are now sadly lacking throughout the country, the disease being as frequently overdiagnosed as it is underdiagnosed¹; (2) facilities for the proper care of patients suffering from rheumatic fever, including hospital beds for the care of acute patients, providing isolation from other patients suffering from hemolytic streptococcal infections, and convalescent care for those with subacute disease; (3) sulfonamide programs for the prevention of recurrent attacks of acute rheumatic fever; (4) a program for the prevention of subacute bacterial endocarditis following tooth extraction or operation on the upper respiratory tract; (5) vocational training of young

patients suffering from rheumatic heart disease so that such patients may become useful citizens instead of public charges.

It was also pointed out at that time that these objectives could be attained by careful integration of community facilities, implemented by a rheumatic registry.² The practical problems to be faced in the organization of such programs were stressed, but it was indicated that these are not insurmountable.

The present (Atlantic City) session was organized to carry forward the concept of the community rheumatic fever program and to indicate its value as an epidemiological tool. This session correlated the interests of representatives of the Sections on Epidemiology, Maternal and Child Health, School Health and Vital Statistics, and was planned in coöperation with the American Council on Rheumatic Fever of the American Heart Association.

Precise epidemiological data concerning rheumatic fever are difficult to obtain, for reasons which will become evi-

* The titles of the papers presented before the American Public Health Association at the Seventy-fifth Annual Meeting are as follows:

The Rheumatic Fever Community Program — Charles A. R. Connor, M.D.

Public Health Nursing in Rheumatic Fever — Mary E. Parker, R.N.,

Medical Social Follow-Up — Florence I. Mosher

Rheumatic Fever and the School Child — George M. Wheatley, M.D.

Principles of the Epidemiology of Chronic Disease — Alexander D. Langmuir, M.D.

† Participants in this symposium were Marjorie T. Bellows, A. L. van Horn, M.D., Ruth E. Lynch, and David D. Rutstein, M.D.

dent as this symposium unfolds. The first essential of an epidemiological study is the identification of individuals suffering from the disease. Dr. Charles A. R. Connor indicated that precise diagnosis of acute rheumatic fever is extremely difficult because heart murmurs of no significance occur in normal people and many of those suffering from the disease have an atypical course. Moreover, the exact etiology of the disease is unknown and there is no specific diagnostic test. Diagnosis is usually dependent on the physician's impression of a group of nonspecific symptoms and signs. The best available criteria for diagnosis are the empirical ones established by T. Duckett Jones.³ He distinguished between major and minor symptoms and indicated that a diagnosis of acute rheumatic fever may be made with relative certainty in the presence of two major findings or one major and two or more minor symptoms.

Precise diagnosis is difficult to obtain on a community-wide basis without the diagnostic facilities available in a community program. The existence of a community program will, therefore, make it possible for the epidemiologist to obtain reliable information concerning the existence of disease in the community and will make it possible for him to secure that information needed for the study of rheumatic fever.

Another essential for epidemiologic study, provided by the community program, is adequate follow-up of those suffering from this disease or those in whom a definite diagnosis has not been established. In a community where a rheumatic registry has been established, this can be provided by the coöperative efforts of the public health nurse and the medical-social worker.

Too often nurses and medical-social workers have concerned themselves with the question of invasion of the rights of one profession by the other, rather than the coöperative activity of the two

professions. This is particularly important in the community rheumatic fever program, because in certain parts of the United States services are provided by medical-social workers which in other areas are provided by public health nurses. In particular, urban services are more likely to be provided by medical-social workers and rural services by public health nurses.

In the New York State program, it was possible to establish a coöperative working relationship between the public health nurse and the medical-social worker. This experience may well provide the basis for coöperative working relationships elsewhere. The plan was worked out in a relatively rural area where a generalized public health nurse system existed and where the role of the medical-social worker was that of consultant, adviser, and educator. Those particularly interested in this problem may read the details of this relationship in the summaries of the papers presented by Mary E. Parker and Florence I. Mosher in Appendix I.

Dr. George M. Wheatley indicated that the school medical service is important in the community program because rheumatic fever causes more deaths than any other disease in children of school age, first attacks usually occurring in this age group, and because it is the most useful screening agency in case finding.

To aid school health authorities in developing a more rational approach in the control of disease, it was proposed that: (1) the school medical examination be improved to aid in more accurate recognition and supervision of rheumatic children; (2) more emphasis be placed on referral by teachers and nurses of pupils believed to be below-par for medical review; (3) less emphasis be placed on restricting the physical activity of rheumatic children, and more attention given to daily observations of pupils for signs or conditions sug-

gestive of rheumatic disease; (4) there be available to school health services and the practitioners diagnostic and consultation services; (5) these services be developed in coöperation with, and by utilization of, existing medical and public health resources in the community.

Dr. Alexander D. Langmuir outlined the principles of the epidemiology of chronic disease as they apply to rheumatic fever. He indicated that the principles of epidemiology were first established through studies of recognized clinical cases of acute epidemic disease and that such principles have been applied to chronic diseases, particularly tuberculosis. He stressed the importance of not disregarding the application of such general principles to the solution of new problems. For example, problems which have been satisfactorily solved in tuberculosis programs have been approached, as far as rheumatic fever is concerned, as if they were entirely new problems. This lack of awareness has handicapped the development of rheumatic fever programs throughout this country.

Dr. Langmuir further discussed the application of the epidemiologic method as exemplified by the studies of John Snow on cholera, and indicated that Dr. Snow, a clinical investigator, had the wisdom to support his clinical observations by the use of epidemiologic techniques which firmly established the principles which govern the transmission of this infectious disease. The added difficulties in the study of chronic disease were then pointed out, with particular

reference to: (1) the need for long-time follow-up; (2) the difficulty in the determination of incidence rates; (3) the use of discovery rates, prevalence ratios, person-years analyses and modified life table procedures; and (4) the problem of the index case. In spite of difficulties in diagnosis and evaluation of vital statistics, it was indicated that a pattern has been slowly emerging which will provide the basis for the explanation of the epidemiology of this disease, and that this has been furthered by the study of epidemics of rheumatic fever in closed population groups. It was emphasized that there was also a need for intensive studies in communities where a rheumatic register (see Appendix II) provides an accurate count and a continuity of observation on all cases, occurring and recurring through the years, in populations that are well defined and measurable.

In the discussion which followed, Miss Jean Downes emphasized the need for the qualitative as well as the quantitative study of chronic disease; Dr. Thomas D. Dublin pointed out that while the community rheumatic fever program would make epidemiologic studies possible, good epidemiologic studies are prerequisite for the development of sound community programs; Dr. Richard Hodges indicated the need for control studies in broad, unselected population groups; and Dr. Samuel M. Wichik emphasized the value of a school health program in providing continuous medical observation of those afflicted with rheumatic fever or rheumatic heart disease.

APPENDIX I

Public Health Nursing in Rheumatic Fever

MARY E. PARKER, R.N.

*Assistant Director, Division of Public Health Nursing, New York State
Department of Health, Albany, N. Y.*

Public health nurses have always given care to patients with rheumatic fever, but adequate and complete service is very difficult, and well nigh impossible unless essential information such as a definite diagnosis and specific recommendation is readily available to them.

In 1942, a diagnostic and consultation cardiac clinic for patients under 21 years of age was established in a rural area in Upstate New York. In connection with this, a follow-up system to insure adequate nursing service was developed.

The cardiac clinic serves three counties, all of which have well established generalized public health nursing services and school nursing services. The generalized public health nursing service in each county is responsible for nursing follow-up. In addition to assisting at the diagnostic and consultation clinic, the public health nurses are responsible for working with the school nurses, social agencies and others in the community concerned with the care of the cardiac child. In fact, they act as liaison between the local physician, the school nurses, the social agencies, the families, and the cardiac clinic.

In preparation for taking on the follow-up of these patients, all public health nurses in the area, including the school nurses, were given a series of six lectures on rheumatic fever. At that time, a convalescent cardiac unit was conducted in one of the state-owned hospitals, and the nurses were given an opportunity to observe the management of rheumatic fever patients, including medical and nursing care, education, occupational therapy, recreation and social service. Opportunity for further learning is furnished at the cardiac clinic.

At the clinic, the supervising public health nurse in the county in which the clinic is located is responsible for the management of the clinic and for the supervision of the public health nurses, the secretary, and the volunteers. An attempt is made to rotate the public health nurses assisting at clinic so that all will have an opportunity to learn more about the management of the child with rheumatic fever and rheumatic heart disease.

The school nurses are encouraged to attend clinic and frequently do so when children known to them are being examined.

All patients must be referred by a local physician. If a public health nurse finds a patient with symptoms suspicious of rheumatic fever, she must refer the patient to his own physician. Only if he requests consultation can the nurse make an appointment at clinic.

When a patient is seen at clinic, a report of the findings and recommendations is sent to the referring physician. The referring physician is advised that the local public health nurse will communicate with him and will give him any assistance she can in the follow-up of the patient. If a definite diagnosis of rheumatic fever is made, the referring physician may request the clinic to provide further consultation in regard to treatment. This is done with the understanding that he will provide interim care. In almost all instances where a definite diagnosis is made, this service is requested and the nurse reports to the clinic physician as well as to the referring physician.

Home visits are made by the public health nurse after she has conferred with the family physician.

The public health nurse is responsible for helping the family to establish a desirable environment for the child who has rheumatic disease. The relationship between streptococcal infections and rheumatic fever must be kept in mind constantly in helping to make any plan for care. What the nurse teaches the family and what help she gives will depend upon whether the child has active rheumatic fever, is convalescing from an attack of rheumatic fever, or has completely recovered to the extent that he can live a normal life. In any particular case, the assistance the nurse gives will depend largely upon the specific recommendations made by the physician.

A report of the items recommended by the clinic physician may help to give some idea of the nurses' job in follow-up. The records of 80 patients with a definite diagnosis of rheumatic disease were examined. Records

of patients with questionable heart disease and congenital heart disease were not included (although the public health nurses gave service to children with congenital heart disease).

In 23 different recommendations occurring a total of 169 times on 80 patients, 28 per cent were concerned with activity of the ambulatory patient; 26 per cent with diet; 10 per cent with bed rest (one-half for active rheumatic fever); 5 per cent with dental care; 4 per cent with avoidance of U.R.I.; 9 per cent with investigation of other conditions; 2 per cent with psychiatric examination; 2 per cent with foster home and convalescent care; 2 per cent with home teaching and school transportation; and 12 per cent miscellaneous items.

A great deal of emphasis is placed upon the more dramatic aspects of care—the care needed during an acute attack of rheumatic fever. Yet, in this particular group of children, it appears that the bulk of the public health nurse's work is helping to provide service which is a part of good child hygiene. This is the kind of care that these patients need most of the time. Only occasionally are special care and special service needed. It is estimated that in this group only about 5 per cent of the children need special care, such as hospital or convalescent care, at any one time. The importance of providing adequate services needed during an acute episode of the disease cannot be over-emphasized, but I think we need to give more thought to improving the nursing services these children need while they are well.

In addition to carrying out specific recommendations on individual patients, the public health nurses have the same functions as they do in any other public health program—namely, case finding, assistance in obtaining medical care, providing nursing care and assistance to the family in obtaining any other services necessary to the rehabilitation of the patient. The public health nurse is not expected to be able to provide all services—in fact, she is not equipped to—but she is expected to be aware of the need for them and to help the family obtain them from the appropriate community agency by coöperative activity with the medical-social worker. These services include education, vocational guidance, rehabilitation and social services—all of which are provided by agencies other than the health department.

In connection with social services, a plan was developed to provide consultation to the public health nurses by a medical-social worker

employed by the State Department of Health. When a public health nurse found a social problem, she referred it to the consultant medical-social worker for advice. Sometimes a conference was all that was indicated; at other times, it was necessary to arrange a meeting with the local social agency to outline a plan for the family; and occasionally it was necessary for the medical-social worker to visit the home with the public health nurse before a decision could be reached. This plan is recorded in the past tense because for the last two years consultation service has not been available. During the time that it was, 9 per cent of the cases carried by the public health nurses were cases that presented serious social problems on which the nurses needed assistance. This figure does not include situations in which the problem was merely one of securing help from an agency to supplement an inadequate diet or to provide funds for hospital or convalescent care. It also fails to indicate the assistance given to nurses by the medical-social worker in staff education programs and in staff conferences. So popular was this service that the scope of consultation expanded to include problems of a social nature encountered by the public health nurses in all of the patients under their supervision regardless of the diagnosis.

If follow-up is to work effectively, it is necessary to keep everyone informed about what is happening to the patient at all times. A system of reporting has been set up whereby the clinic physician has a complete report of the patient's progress between clinic visits, and the nurse is kept informed of the physical findings and the recommendations. Only one record form is used for this and is shuttled back and forth between the clinic and the public health nurse. The referring physician receives a report each time a patient under his care is examined at clinic and he is also given a report of the visits by the public health nurse.

Any follow-up system, if it is to result in adequate service to the patient, must provide for a method of coördinating the work of the agencies giving services needed by the rheumatic fever patient. Included in this are hospitals, convalescent homes, clinics, private physicians, public health agencies, social agencies, educational and rehabilitation services.

Unless there be a coördinated plan for care, the public health nurses will have difficulty in carrying out their responsibilities in a rheumatic fever program.

Medical Social Follow-Up

FLORENCE I. MOSHER

*Medical Social Consultant, Association for the Aid of Crippled Children,
New York, N. Y.*

With the broadening of public health programs and the development of medical care programs on national, state, and local levels, the scope of medical-social service has widened. The fundamental responsibility of meeting social needs remains the same, but the application of principles and techniques is related to medical care for a large number of patients. In many of these programs, a medical-social worker functions as a consultant and does not duplicate the services of social workers in other social agencies, of hospital social workers or public health nurses.⁴ She assists the administrative personnel in program planning to insure consideration of social factors pertinent to the provision of medical care; gives consultation services to the staff on individual and group problems that have social implications; promotes the development of coöperative working relationships with community agencies in the fields of welfare, education, rehabilitation, recreation, hospital social service and convalescent care, so that their services may be utilized to the utmost in meeting needs related to illness, medical care, and positive health for the community.

There are frequent references in medical literature to the similarity of the problems and the management of tuberculosis and rheumatic fever. Community organization programs for tuberculosis have been suggested as guides for the development of similar programs for rheumatic fever.⁵ About one year ago, the U. S. Public Health Service sent out a publication entitled "Medical Social Service in Tuberculosis Control"⁶ which discusses the functions of the medical-social worker in that program. There is a striking similarity between the described activities in that pamphlet and the pattern of medical-social service developed a few years ago as a part of the program of the Cardiac Bureau in the New York State Department of Health. A cardiac service for the care of children with rheumatic fever was established at the New York State Reconstruction Home and has been described in the paper given by Miss Parker. The basic philosophy of medical-social service programs can be applied to a rheumatic fever community program, as outlined by David D. Rutstein⁷ in a paper read at a symposium on

"Rheumatic Fever," and by the Public Affairs Pamphlet⁸ on rheumatic fever.

The medical-social worker functioned as a consultant and gave direct case work services when referrals were made by the public health nurse or doctor and there were no community resources available to give such services. She was responsible for compiling data about the community agencies which provide social services for that area. In instances of duplication of agency programs, she assisted in promoting the realignment of their services. The medical-social consultant helped with the development of coöperative working agreements with agencies. Through her liaison activities, she strengthened the integration of agency services toward the maintenance of a well rounded program. She was able to indicate need of new resources as she became aware of unmet community needs as well as to help improve existing facilities.

In the diagnostic clinic, the medical-social worker acted as a consultant to other staff members. She assumed direct case work responsibility when requested by physician and public health nurse and when facilities were not available in the community. One of her major functions was the uncovering, evaluating, and assisting in the adjustment of emotional fears, economic stresses, and social problems that prevent acceptance of diagnosis and recommended treatment. Whenever several members of the medical team were concerned with a complicated social situation on the same case, there was a conference and agreement upon the responsibility each would carry. When a health problem was predominant, the public health nurse assumed the leadership. When there were both health and social factors, the case was carried by the public health nurse with consultation from the medical-social worker. If the social factors were predominant, case work services were requested from the proper community agency. Joint conferences of public health nurse, medical-social worker, and agency representative insured good planning and services for the patient and his family.

In the rheumatic fever community program, the medical-social worker assisted in the development of standards to be used for deter-

mination of the ability of parents to participate in financial arrangements for medical care which would permit the maintenance of a reasonable standard of living and help retain a stable family unit. Interpretation of the illness and the medical recommendations to welfare departments helped them to recognize the need for providing medical care for rheumatic fever patients without penalizing the family who can manage to meet their current expenses. Because of the chronicity of the disease and with long-time bed rest the only effective treatment, it was imperative that the family maintain good living conditions and emotional balance.

Since the acute rheumatic fever patient may be hospitalized, there was close coöperation with the hospital medical-social worker. In order to have good continuity of care, there was interchange of medical and social data between agencies providing services for the patient and his family. While he was in the hospital, unfavorable home conditions were adjusted if possible.

When the rheumatic fever patient was ready to leave the hospital, the physician, public health nursing consultant, medical-social consultant, and hospital personnel worked out a plan of convalescent care that was determined by the total situation. If the patient's home were unsatisfactory due to substandard housing or emotional factors, his placement in a

cardiac unit or a foster home was decided on the basis of his needs. Educational, recreational, and vocational services were also important at this time.

When the patient returned home, the public health nurse gave follow-up service with the medical-social consultant giving consultation service when needed. It was necessary, from time to time, for the nurse and medical-social worker to have joint conferences with welfare or other agencies for better understanding of the total family situation and to reach an agreement regarding services the respective agencies were to provide for the patient and his family with emphasis on alleviation of factors that cause recurrence of the disease.

Although the opportunity was not provided in this program, a medical-social worker can function effectively in social research relating to community health and medical care programs. In a rheumatic fever community program, she could have ample opportunity to collect data regarding the effects of inadequate housing, income, diet, and psychologic factors. Further data could be obtained regarding the greater number of recurrences occurring when a child convalesces in his own home. Studies might disprove this statement if all needed services were available and a well rounded program could be provided for the patient and his family while he remained at home.

APPENDIX II

The Registry in the Community Rheumatic Fever Program

MARJORIE T. BELLOW, F.A.P.H.A.

Statistician, American Heart Association, New York, N. Y.

The primary function of a register is to implement with specific mechanical procedures the program of service to rheumatic patients. There are, however, certain prerequisites of a program which are particularly essential to the development of a register. First, there must be agreement by the medical profession and all agencies to centralize responsibility for integration of the program. This discussion is based on the assumption that there is a central agency from which procedures governing the entire program can emanate and where the register which controls such procedures can be located. A second essential condition is that there be accepted standards and criteria for adequate service. Such criteria have

been set up for cardiac clinics, but there should be similar guides for appraising the quality and adequacy of all services and facilities. There should also be minimum standards for the frequency and kind of care and follow-up required by each type of patient to be included in the program.

The obvious first procedural step in instituting a program is to survey all community resources in order to appraise existing facilities as to volume and quality and to determine which groups of the population are receiving care and the effectiveness with which they are served. Such an appraisal of resources makes it possible to discover where existing services are inadequate and where overlapping and

duplication occur. On the basis of this information, it will be possible to outline a program which will utilize fully both existing facilities and whatever supplemental service can be made available.

The next step in organizing a program is to set up continuing checks to see that specific objectives are being carried out. This means, first, that there be available a perpetual inventory of facilities and, second, that there be automatic checks to see that every patient is getting the service intended. A resource file is suggested as a possible mechanism for maintaining current information regarding facilities and services. A case registry is the device which has been found in other chronic disease programs to be essential for case management. Both may originate in a community survey and both can be maintained by a system of routine reporting and regular follow-up.

RESOURCE FILE

The resource file is essentially a device for showing the volume of facilities available to carry out the objectives of the program. In smaller communities where treatment, care, and follow-up agencies are few in number, it might not assume quite as much formality as is implied in its name, but, in all communities, there should be an organized method for obtaining answers to very important questions which relate to program planning and case referral. Certain facts which should be easily obtainable from the resource file can be listed as follows:

1. The capacity of existing facilities and their quality as measured by accepted standards.

2. The extent to which these facilities are being utilized (for example, the number of patients being served annually by each agency). Ideally, the central integrating agency might attempt to keep current information as to the numbers and locations of vacancies for such facilities as beds for acute care. It might prove difficult, however, in large metropolitan areas to keep such information current.

3. The economic selectivity of existing facilities—in other words, the resource file should supply data showing how much service is available to patients who are able to pay for it and how much to patients regardless of their financial status.

Such an analysis of resources will be derived, in the first place, from a survey. It can be maintained by a combination of periodic reports to the integrating agency and follow-up procedures in the field.

The initial survey will require careful plan-

ning to see that all agencies which are concerned in any way with rheumatic patients are included. As in all surveys, there must be prepared forms specifying exactly what information is desired. Such forms should be sent out at approximately the same time and followed up to make certain that the survey is complete. Maintenance of the file requires reporting forms, regulations for reporting, and follow-up. Special summary sheets or tabulation forms should be devised so that information may be tabulated regularly and summaries compiled whenever they are required. This describes, in general terms, what should be done, but field experimentation should result in detailed forms and directions or manuals of procedure for setting up and maintaining a resource file.

CASE REGISTER

The case register is a file of summary cards—one for each individual who requires service under the rheumatic fever program. It is a cross-index, on a case basis, of all services in the resource file, in that it shows for every patient, the persons or agencies who are giving service. It also shows for each patient his current diagnostic, therapeutic, and functional classification; where he is located; his occupational or school status; and who is responsible for his care. These are minimum requirements and, depending on the program, other items may also be required.

The functions which a case register can serve are as follows:

1. It is an index of all known cases. Newly reported cases can be checked in this file as a first step in verification of diagnoses and to find out whether or not they have had previous treatment and, if so, where and from whom.

2. It makes available in one place, to any agency concerned, a means of locating all existing detailed information on a specific case.

3. It can show where duplications of service are occurring and eliminate overlapping of service.

4. It provides, at a focal point, enough information for an individual case to reveal deficiencies in care or supervision.

5. It can serve as a mechanical device for directing follow-up activities. Cards can be flagged to show automatically which cases need some sort of follow-up and by whom.

6. It will provide statistical data which will aid in developing and planning the overall program and help in evaluating the effectiveness of the program.

As to information to be included on the

individual register card and how it may be obtained, this depends, to a large extent, upon the program itself. For purposes of this discussion, it will be assumed (1) that the program includes some system of case reporting into the register which will provide a source of information as to the location of new cases; (2) that there are criteria established for acceptable diagnoses and provision for verification of those that are not acceptable; (3) that every case will be followed up immediately after first report by field personnel; (4) that there is some system of interim reporting on admission to and discharge from service by all agencies concerned in order to keep case information current; (5) that there is routine follow-up of cases who have not been reported on for certain periods of time as an additional procedure to maintain currency of information. Indeed, unless these five conditions are met, the wisdom of setting up a community register might be seriously questioned.

The initial report will supply basic identifying data such as name of patient, name of parents or guardian, address, age, sex, color, marital status, and present location, together with the diagnosis at time of first report, the reporting agency, and date of report. This is the kind of information ordinarily included on forms for reportable diseases and represents about the maximum that can be required or relied upon from an initial report.

Previous history of rheumatic fever (with dates), occupational or school status, and agencies at present giving care should be obtained through some form of follow-up such as a nursing home visit or letter to the physician.

Follow-up data showing, with dates, most recent diagnosis, present location of patient, agency at present responsible for medical supervision, other agencies giving advice, and current occupational and school status, should be obtained from interim reports and can be recorded on the register card in table form chronologically as reports come in. In the absence of such interim reports, provision should be made for some kind of periodic check with the agency responsible for supervision to keep information on each case reasonably current.

The register may be set up initially either by surveying all agencies who may have responsibility for patients and abstracting case records, or by building it gradually from routine case reports. Since in the latter case it is difficult to know when or if the register is complete unless a check survey is made, it seems as if a case survey made at the same time as the resources survey is preferable. Whenever a case survey is done, there should

be provision for follow-up of all cases where complete information is not obtained.

As to maintenance of the register, systematic reporting will do much to keep information current and will cut to a minimum the amount of follow-up required. The following types of reports are suggested as basic:

1. Reporting of all newly diagnosed cases by physicians, clinics, and hospitals.
2. Reports of changes in diagnosis by physicians, clinics, and hospitals.
3. Admission and discharge reports from all institutions and agencies.
4. Report of all deaths from rheumatic fever and from heart disease within a certain age group by the vital statistics agency.
5. Reports from school health services of children suspected of having rheumatic fever or rheumatic heart disease and those admitted to special classes. In addition, there should be reports of children changed from special to regular classes.
6. Reports from follow-up agencies, such as medical-social workers and nurses.

For best control of the program all reports of new cases should be reviewed by a physician in order to classify the diagnosis, and to make whatever initial contact with reporting physicians may be necessary. At certain intervals, every case summary should be reviewed by a physician to determine whether or not routine procedures are operating effectively. A decision should be made after every additional report on a case as to when it next requires follow-up and by whom, and, at this time, the card should be marked with a signal in some way to show when the next follow-up report is due and from whom it is due. Procedures should be established for notifying, automatically, the agencies concerned that some action is required. Forms to specify what new information is desired and what action is to be taken can be developed. There should be, also, regulations as to what type of information is to be forwarded to other agencies routinely, and report forms to facilitate transfer of information from the registry to other agencies should be drawn up.

It might be wise, at this point, to emphasize that definite limiting conditions should be placed on admission to and discharge from the register in order to prevent it from becoming unwieldy and inefficient. There must be established policies or rules specifying what cases are to be included in the current register and when they are to be discharged as non-current and for what reasons. From a realistic standpoint, the current register can

include only those cases who are being followed up at regular specified intervals, and about whom information is being kept current. The program itself and the amount of service that can be given will determine which cases are followed up and are, therefore, to be included in the current file and when they are to be discharged from follow-up and from the active register. Mere faith that patients who ideally should be followed up will somehow be seen or heard from, and trust that dead wood will eventually drift out of the register, are certain means of acquiring a large unmanageable file of meaningless records. There is no magic by which the register can be more inclusive than the follow-up program itself.

There are a number of mechanical systems on the market that are easily adapted to registers of the sort described. Visible files are certainly the most efficient where there are less than 2,000 cases, since the visible edge can be used for indexing, signalling, and for coding statistical items which will need to be counted frequently. For larger files, punch card systems can be adapted to do all that visible files will do on a smaller scale.

By way of summary, it should be emphasized that the filing and reporting systems outlined have not been field tested, nor can they be considered final recommendations in any sense. They are not, however, in any way unique to rheumatic fever programs. Any chronic disease program requires very similar mechanisms and excellent ones have been worked out, notably by persons working in the tuberculosis field.^{9, 10} It might be wise to remember that no mere mechanics will be suc-

cessful in developing a sense of community responsibility for cases of rheumatic fever and rheumatic heart disease, nor will they shape an effective rheumatic fever program. They can only provide a mechanical basis for, and implement a program which has been accepted by professional and lay members of the community and one which has clearly defined objectives, specifically stated standards for care and follow-up, and adequate personnel to see that these standards are met.

A Medical-Social Worker's Approach to the Problem of Poliomyelitis*

ETHEL COHEN

Director, Social Service Department, Beth Israel Hospital, Boston, Mass.

A SOCIAL component exists in every illness in so far as the illness disturbs the usual normal activities of the patient. The extent of this interference may range all the way from a minor inconvenience to a major breakdown in an entire way of life. Illness thus influences the patient's environment, his relationships, and his feelings of adequacy as a human being. People differ from each other constitutionally and psychologically. Diseases affect human organisms variously. The development, progress, and final outcome of many illnesses are influenced by factors outside the disease process itself. Reactions to a given illness in different individuals will be determined by their diverse constitutions and personality structures, and by their economic and social circumstances. The interplay of all these elements produces the individual illness situation for each person. Therefore, the care of the whole patient, rather than treatment of the disease only, becomes the aim of all the professional workers involved.

These principles are very well known, but unfortunately in times of crisis or pressure their application in practice is often unnecessarily sacrificed. All the professional workers are members of a team of which the physician is the chief. While each worker has a specific function based on a particular skill for

which he has been trained, all have some degree of social responsibility. The medical-social worker, because of her particular training and skill, has the major social function. It is generally recognized that this worker helps individual patients deal with the social and environmental elements in the health problem, and assists him to make the most effective use of medical care and related health services. She is also concerned with administrative policy as it affects the patient. Too often hospitals and other medical agencies unintentionally create problems for patients through failure to consider social factors in program planning and policy making. In organizations where the medical-social worker has been part of the team while administrative policies were being created, many of these difficulties have been anticipated and avoided.

Poliomyelitis presents special problems arising from its natural history, and from certain unsolved clinical aspects. People have a unique dread of this disease. Its cause is unknown. Its onset is sudden and dramatic; the outcome unpredictable. Its effects are often swift and irreversible. The greatly publicized controversies about methods of treatment have often aroused doubts and loss of confidence in the particular treatment prescribed. During epidemics, panic is widespread. Families of patients are naturally anxious. Superstitious fear on the part of the general public intensifies prob-

* Paper presented at Georgia Warm Springs Foundation, September 16, 1947, at the clinical conference in commemoration of its 20th anniversary.

lems of caring for patients and their families. These emotional and environmental factors are inseparable from the problems of care and treatment. If adequate social consideration is unavailable, eventually these severe emotional experiences may be expressed in various ways to the detriment of the patient. The separation of patient and family during the isolation period, without reasonably adequate information about the patient's condition, causes parents to become agitated and even hysterical. They may insist on removing the patient from the hospital against advice during the acute phase. Others may wish to postpone indefinitely the patient's discharge. This may be due to rejection of an unwanted child, or to inability to face the new difficult situation, or to fear that the patient's care will be overburdensome.

The following illustration¹ was reported by a U. S. Children's Bureau consultant on visit to a state during an epidemic:

The worst epidemic of poliomyelitis in years had hit the state that August. From farms and little towns parents brought their sick children in jalopies, trucks, and wagons along the hot, dusty roads to the city for treatment. The hospital wards were overflowing, and physicians, nurses, and attendants worked night and day to care for the polio victims. Rooming houses and auto courts, afraid of the disease, refused to accept the parents, many of whom camped in their cars and waited day after day for word of their children. Families were frantic. Some parents secured ladders so they could climb up to the hospital windows and look in. In one family, the mother and three children had been stricken—the grandmother stayed outside the isolation hospital keeping vigil. In another family five members had been stricken. The weary and anxious father kept his post outside the hospital day and night.

Doctors were too busy to talk to anxious parents, regarded as a nuisance by the overworked hospital staff. All non-polio patients, that could be moved, were to be sent home, but no response had been received from several parents. . . . The medical-social worker

assisted in the discharge of these patients, bearing in mind that no child should be discharged to unsatisfactory home conditions which would hinder his recovery. . . .

Problems of family relationships were recognized as the main concern of the medical-social worker, who talked with each parent to ease his anxiety and to learn about his ability to care for the child at home. Some parents would cease their futile waiting and return home if assured of regular reports about the child's condition; other parents who needed to remain close to their children were helped to secure proper living accommodations through the State Welfare Department, Salvation Army, and service clubs.

. . . Community agencies, when given leadership, rallied to give the parents shelter. Many parents returned home. One father confided that he had lost a leg in a childhood accident and feared that his son, of whom he had been so proud, would be a hopeless cripple. He returned gratefully to his duties on the farm when assured that the child's involvement was slight and that he would be kept informed of the boy's condition.

A father, whose wife had a serious heart condition, had been frantic because the family could not give his little girl the attention recommended when she would return home. His relief was tremendous when told that convalescent care in a foster home would be arranged. . . .

These circumstances in one undeveloped rural community are familiar to all workers outside of large metropolitan areas. However, they are not unusual even in cities. Experiences of the same type, though of different quality, in a highly organized teaching hospital were reported in published accounts² of the 1943 Connecticut epidemic.

Social services for patients and their families are needed at the time of an epidemic. One of the problems frequently is to assure plans for beds required for the acutely sick polio patients. Major problems for social service are the anxiety of parents, their readiness to incur expenses impossible for them to meet in order to get care for their child; fear in their communities and the refusal to have any contact

with the families in which poliomyelitis has developed; lack of attention to the emotional needs of children receiving care in a hospital ward where personnel are greatly overworked; failure to establish a means of direct communication between doctors and parents; adequacy of the home for care, if the child is not sent to a hospital; and also the development of undue strains on family relationships.

Community plans for children with infantile paralysis should be well developed in advance so that responsibility for standards and adequacy of *all* phases of care is established and carried by a responsible agency, preferably a health department or other official agency working coöperatively with the health department. This is advised because various parts of service are frequently provided by different agencies. As a consequence gaps or overlapping services result without ultimate responsibility carried by any one agency. The coördination and integration of all the medical and auxiliary community social services are urgently needed to insure best care for the patient and the most advantageous and economical use of resources.

Viewing the country as a whole, there exists an infinite variety of community organization and medical settings, with equal diversity in numbers and types of professional workers. To enumerate a few, among them are clinics of public programs, both permanent and itinerant, public hospitals on state, county, and municipal levels; voluntary hospitals, some of them affiliated with medical schools, proprietary hospitals, convalescent, nursing, and chronic homes. Inasmuch as all the necessary personnel are not present as a rule in any of these institutions, one can only suggest principles to guide, rather than recommend specifically the relationship of the medical-social worker and her professional coworkers. The medical-

social worker may be in a hospital giving direct service to patients and families; or a consultant to other members of the medical team or to non-medical community agencies. In either setting, knowledge of the social aspects, shared by the medical-social worker with her professional coworkers, increases their capacity to carry out their own responsibilities. The medical-social worker in turn has much to learn from her coworkers. In fact, the insight she gains from a knowledge of the others' activities often gives her greater understanding for her own work in a given situation.

When the acute phase of polio passes into the convalescent stage, many different problems arise for the patients left with paralysis. The need for continuous care of many weeks, months, and often years is a challenge to patient and family. The normal place for a patient is in his own home. Adequacy of a home is determined by considerations of distance from treatment center, physical facilities, economic security, health, intelligence, and emotional attitudes of the family. The feelings of the parents toward the child and his sense of security may influence the duration and extent of his incapacity. Parents must have the willingness, intelligence, and freedom from other family and personal complications to coöperate in home treatment, persist in exercise, encourage the patient to activity, self-help when crippled, and adjust to cumbersome braces. The sight of a crippled child or adult often arouses strong negative feelings in relatives, as well as in other associates or strangers. Some crippled children are extremely sensitive to their appearance and its effect on others. We have all seen the patient who feels himself conspicuous and handicapped by a slight foot drop, while another patient with a completely flail leg may make a normal adjustment.

The community has the responsibility for providing substitute arrangements, when the home is unsuitable for the patient's care. Few if any communities seem to have enough of the proper kind of convalescent homes, particularly for the adolescent and young adult. Convalescent institutions or foster homes become for many patients their only real home for long periods of time. Therefore, these facilities should provide a friendly, warm psychological atmosphere, good physical care, opportunities for development through education and recreation. The serious weakening of some family ties can occur quite easily. Frequent visiting hours for relatives, in addition to correspondence, are necessary to keep alive the bond between them and the patient. Otherwise children feel they are not loved or wanted at home. Many institutions consider relatives' visits annoyances and interrupting to their routine. With more imagination in administrative planning, the needs of the patient in this respect can be safeguarded without undue sacrifice by the management of the institution.

For children in some communities care must be provided in foster homes through the help of child welfare agencies. The necessity to plan resources for the chronic patient with complete and permanent disability is too well known to require further elaboration here, but is of sufficient importance to warrant this brief comment.

During the convalescent period, patients and relatives are confronted by new anxieties. They need careful interpretation of what convalescence will involve, a description of the place to which patients are being sent, and some estimate of the duration of their stay. As one worker put it, otherwise some patients get very "queer" ideas. Some, severely crippled, think they will walk at the end of three months, and can return to their former work. Others, dur-

ing long-time convalescence, feel isolated, and believe their relatives have rejected and abandoned them. Antagonism and severe emotional upheaval often result when unprepared patients learn the truth finally about their permanent crippling and disability. As soon as medically feasible, contact with the State Rehabilitation Agency may bring adolescent and adult patients new interests and hope of work and self-support for the future.

My personal observations in crippled children's clinics of several states left an enduring impression of the fortitude, physical strength, and patience needed by parents and patient alike. The sacrifice in normal personal social life for many parents is enormous. However, some lack the required intelligence and skill to deal with the discouragement and rebellion of the crippled child.

All professional personnel, doctors, nurses, physical therapists, teachers and occupational therapists sometimes encounter resistance in various degrees in their efforts to help patients. Most well trained personnel in all fields now have some instruction in the principles of human behavior, and something of the social aspects of illness. This insight is indeed helpful, but is not a substitute for the services available from a trained medical-social worker whose functions are social study, services to patient, and integrated work with all the other professional coworkers.

To get maximum benefit from treatment, the patient must be treated as a whole. The best way to achieve this is by regular frequent conferences of all involved in his care, each contributing from his special field and jointly deciding what role each will play. A procedure which has yielded excellent results in medical teaching hospitals and rural clinics alike is the joint group review and evaluation of a patient's problem. The results of such conferences become more than the sum of all

the individual contributions, for the give and take among the various workers often produces a new idea which no one person might have conceived by himself.

At times all of the specialized personnel participate simultaneously. At other times, the role of certain workers predominates and the others are less active. This requires a high degree of coöperation and understanding of each other's function, as well as clarity concerning each individual's own function. All have some social responsibility; none may relinquish a share of such responsibility, but to the medical-social worker should come the problems requiring social treatment, knowledge of community resources, not only of their existence, but of their specific services. As a social worker, she should know what can be expected of these resources; how to select the most appropriate from among those available, or how to improvise resources where no adequate professional agency exists.

The relationship between the medical-social worker and other professional coworkers may be exemplified, as follows: During certain stages of the illness, the physical therapist may be seeing the patient more frequently than any other member of the team. She has the opportunity to observe the patient's behavior which may be symptomatic of personal problems. She can best serve

the patient and family, not by advising them how to deal with the apparent social problem but by sharing her observations with the medical-social worker, whose special training enables her to deal with the social difficulties. Discussion of the problem, when a patient first begins to lose interest in learning his exercises, may prevent the crisis in which he refuses to continue treatment altogether. Conversely, if a medical-social worker observes a patient exercising incorrectly, she has the responsibility to act. This would not be by instruction to the patient, but by relating her observations to the physical therapist within whose province this problem belongs. If all members of the team would correlate their services in this way, some difficulties in process of development might be overcome before they crystallize.

Each worker, by appropriate use of other services, frees himself for maximum service in his own specialized field. Such professional practice should result in the best care of the individual patient, and the most productive and economical use of the community's investment in its health and social agencies.

The Economic Status of Public Health Nurses, 1946-1947*

DOROTHY E. WIESNER AND LILY MARY DAVID

*National Organization for Public Health Nursing; and Wage Analysis Branch,
Bureau of Labor Statistics, Washington, D. C.*

THE average public health field nurse earned \$2,290 a year while supervisors received \$3,040 and directors of public health nursing services averaged \$3,292 annually in 1946-1947. These salaries were paid for an average work week of 40 hours. These hours included some overtime, reported by substantial groups of nurses; in a majority of cases they received compensation, generally in the form of time off, for this work beyond regularly scheduled hours. About 3 out of 10 public health nurses were subject to call for some time in addition to their hours on duty.

Out of their salaries, public health nurses spent an average of \$83 during 1946 on professional expenses. About 1 in 7 incurred professional expenditures of more than \$200 annually.

Almost all public health nurses receive paid vacations and sick leave after a year's employment. Typically, vaca-

tions are for 2 to 4 weeks. Only a minority of public health nurses benefit from retirement pension plans, however, and only 1 in 6 is provided with hospitalization, medical care, or periodic physical examinations at the expense of the employing agency.

The major complaints of public health nurses were economic, including problems of provision for retirement and employment security, rates of pay, methods of awarding promotions and pay increases, and opportunities for promotion.

SALARIES, APRIL, 1947

Salaries in public health nursing are influenced by many factors. Some of these variations which can be easily observed are: position on staff, type of employing agency, part of country, and size of staff.

Generalized field nurses—The median salary among more than 7,000 field nurses was \$2,290 per year. The range

* This article is based on two studies—the economic study of the nursing profession conducted by the Bureau of Labor Statistics of the United States Department of Labor early in 1947, and the 1947 Yearly Review of the National Organization for Public Health Nursing. The former study was conducted by a mail questionnaire filled out by about 1,350 public health nurses. These represent about half the public health nurses who received questionnaires and over 6 per cent of all 21,000 nurses active in this field in the United States. Replies were received from every state and from nurses employed in both governmental and non-governmental agencies.

Almost 650 public health nursing agencies returned Yearly Review schedules to the N.O.P.H.N.; 1,200 schedules were mailed. The Yearly Review contains sets of questions about which N.O.P.H.N. needs answers, salary data being one of the most important. The columns for salary data are arranged so that information is available by position on staff, by annual

basic salary, and by cost-of-living adjustments. The salary figures used in these paragraphs include cost-of-living adjustments. Data are given for the following kinds of agencies: public health nursing services in 36 state health departments; 112 county health departments; 87 municipal health departments; 122 boards of education; 255 nonofficial agencies; and 29 combination agencies. Salaries for sixty-five kinds of full-time jobs were tabulated. Among nurses, some of these were directors, educational directors, generalized supervisors, specialized supervisors, generalized field nurses, specialized field nurses, trainees, practical nurses and others, the total number being 10,351. Among non-nurse professional workers connected with public health nursing staffs were nutritionists, social workers, statisticians, non-nurse physical therapists, and others; such workers numbered 209. Clerical employees in these agencies numbered 1,414. All salary information was for the year ended April 1, 1947. Average salaries used in this article are medians.

of such salaries was from \$1,200 to \$3,790. The median salary for field nurses was highest among those employed by city health departments, \$2,527; next came those in boards of education, \$2,481; third, \$2,265 in county health departments; fourth, \$2,243 in combination agencies; fifth, \$2,178 in state health departments; and lowest, \$2,161 in nonofficial agencies such as visiting nurse associations.

The 9 divisions of the United States, as outlined by the U. S. Bureau of the Census, were used for this salary study. Agencies in the Pacific Coast states paid their generalized field nurses better than did those in other parts of the country. Agencies in the South Atlantic states paid lowest salaries. The greatest differences between high and low salaries appeared among the state health department nurses, the median for generalized field nurses on the Pacific Coast being \$3,050 and for those in the East South Central states, \$1,837. Board of education salaries also varied widely, averaging \$2,783 in the Pacific Coast states and \$1,872 in the South Atlantic states. Salaries in nonofficial and combination agencies varied less by part of the country than did those in other kinds of agencies.

For the most part, generalized field nurses in large agencies were better paid than were those in small ones. However, in nonofficial agencies the worker in the one-nurse agency was better paid than those employed in most of the medium sized agencies. This is to be expected, since such a nurse should have more experience as she has little direct supervision. She also needs ability to work with her board and with the community.

Generalized supervisors—The range for supervisors' salaries in 1947 was from \$1,920 to \$4,620. The median salary was \$3,040. Salaries of generalized supervisors exceeded those of generalized

field nurses by the following percentages, as measured by the medians secured from the figures for the various kinds of agencies—in municipal health departments, 32 per cent; in county health departments, 27 per cent; in boards of education, 20 per cent; in state health departments, 39 per cent; in nonofficial agencies, 35 per cent; and in combination agencies, 22 per cent.

Directors of public health nursing services—The range of directors' salaries was from \$1,900 to \$9,500. The median salary was \$3,292.¹ The number of nurses employed in the service affects the directors' salaries more than does any other single factor, the salary increasing as the size of the service increases. Directors' salaries were higher in nonofficial agencies than in other types of services. Agencies employing 15 nurses and more were used to show comparisons of directors' salaries with supervisors' salaries. Directors' salaries exceeded those of supervisors by the following per cents in the various kinds of agencies: in municipal health departments, 12 per cent; in county health departments, 21 per cent; in state health departments, 32 per cent; and in nonofficial agencies, 48 per cent. Median salaries for each position were used for these comparisons.

Non-nurse professional workers—Among 69 nutritionists, the median salary was \$2,890; among 29 social workers, \$3,060; among 26 statisticians, \$3,043; and among 20 physical therapists, \$2,486.²

Full-time clerical workers—The range of annual salaries paid to 1,414 clerical workers reported on the Yearly Review schedules was from \$780 to \$4,500. The median salary was \$1,816. These figures also included any cost-of-living adjustments paid during the 12 months ended April 1, 1947. The median sal-

ary for generalized field nurses was \$2,290, which is 26 per cent above the median salary for clerks. About one-half of all the clerical workers received from \$1,550 to \$2,100.

Table 1 shows the kinds of clerical jobs listed on the schedule sent to the agencies, the number of each kind for whom salary data were given, and the median salaries for these groups.

TABLE 1

| <i>Position</i> | <i>Number for whom salary data were received</i> | <i>Median annual salary</i> |
|------------------------------------|--|-------------------------------------|
| Total clerical workers | 1,414 | \$1,816 |
| Bookkeeper | 55 | \$2,047 |
| Clerk | 520 | \$1,692 |
| Registrar | 27 | \$1,950 |
| Secretary | 197 | \$1,933 |
| Stenographer | 188 | \$1,860 |
| Switchboard operator | 16 | \$1,692 |
| Typist | 134 | \$1,676 |
| Various kinds of work ^a | 190 | \$1,750 |
| All others ^b | 87 | \$2,111 |

^a Bookkeeper and secretary; clerk and stenographer; etc.

^b Statistical clerks; office manager; file clerk; insurance clerk; supply room clerk; receptionist etc.

Clerks working in Pacific Coast states received higher salaries than those in other sections of the country, their median salary being \$2,082. Clerks in the west south central states received low salaries, \$1,407 being the median. In all the southern states, clerical salaries were low, and also in New England. In the latter area, among 148 clerks, only 5 received \$2,160 or more, and 44 received less than \$1,440. Salaries of nurses varied rather similarly as to geographical areas, being highest in the Pacific states. In New England, however, only salaries in nonofficial agencies were markedly low.

Clerical salaries were higher in agencies employing 25 nurses and more than in the smaller agencies. Among 756 clerks in these larger agencies, the median salary was \$1,887; among 368 clerks in agencies employing less than 10 nurses, the median salary was \$1,645. Only 5 of the 23 full-time clerks in

one-nurse agencies were paid more than \$1,560 a year.³

HOURS OF WORK, OCTOBER, 1946

Weekly hours of public health nurses are shorter than those of most members of the nursing profession, and are generally on a level with the peacetime hours of most workers in the United States. However, like those in hospital work, some public health nurses are required to be on call beyond their regular time of duty.

Late in 1946 the typical public health nurse worked on a schedule of 8 hours a day and 40 hours a week or less; such schedules were reported by 7 out of 10 respondents. Schedules of less than 8 hours daily and 40 hours weekly, however, were frequent, being reported by half the school nurses and one-third of the other public health nurses. As Table 2 indicates, schedules of more than 44 hours were rare:

TABLE 2

| <i>Work Schedule</i> | <i>Per cent of Nurses</i> |
|---------------------------------------|-------------------------------|
| Less than 8 hours a day and 40 a week | 36 |
| 8 hours a day and 40 a week | 34 |
| 8 hours a day and 44 a week | 21 |
| 8 hours a day and 48 a week | 2 |
| Schedules not reported | 7 |

Actual hours of the public health nurse averaged 40 a week during October, 1946.⁴ Comparison of actual and scheduled hours indicates that a significant proportion of the nurses worked some overtime.⁵ Thus, although schedules in excess of 44 hours a week were uncommon, about 1 in 10 nurses worked 45 to 49 hours and another 1 in 20 was actually on duty over 50 hours a week. Of those who worked overtime, about 3 out of 5 received some compensation for this work, generally in the form of time off rather than additional cash pay.

A complete picture of working time is not provided by hours on duty alone, since about 3 out of 10 public health nurses reported that they were required

to be on call for some time in addition to their regular hours on duty during October, 1946. Typically they were subject to call for less than 20 hours during the month studied and actually were called to duty for less than 10 of these hours.⁶ Thus, time on call amounted to about 10 hours a month beyond time on duty for those nurses required to be on call. A few, presumably those who were the only nurses in small communities, reported more than 100 hours a month on call.

The Pacific Coast and the Middle Atlantic and Mountain states showed the shortest hours of work. The longest hours were found in the west central states, in which the average public health nurse was on duty about 43 hours a week in October, 1946. Hours on duty varied less among different types of public health agencies than did salaries. The longest hours were reported by county official nurses and the shortest by those working for federal and municipal governments; many of the latter are school nurses, who work less than 40 hours a week. The requirement of time on call was most common in non-official agencies.

PROFESSIONAL EXPENSES

During 1946 the average public health nurse spent \$83—about \$7 a month—for professional expenses. These

included purchase of professional equipment, membership in professional organizations, laundry, cleaning and purchase of uniforms, state registration fees, payments to nurses' placement registries, and expenses of transportation during working hours, not reimbursed by the employing agency. These average expenses were equal to those for all other fields of nursing considered together, although a comparatively high proportion of public health nurses (more than 1 in 7) reported annual expenses of \$200 or more. Presumably this group includes nurses who were required to maintain a car or pay for other transportation on the job out of their salaries. Expenses were somewhat higher for municipal and county official employees than for other public health nurses.

VACATION AND SICK LEAVE PLANS

Almost all nurses in the public health field receive paid vacations and sick leave after a year's service. Vacations in almost every case are at least 2 weeks long. The number reporting vacations of 2 weeks is equal to the number receiving 4 weeks or longer; 4 out of 5 nurses report these two periods. The longest vacations are provided federal government employees, who receive 26 working days of such leave annually, but most nurses working for nonofficial

TABLE 3

Annual Paid Vacations of Public Health Nurses with One Year's Service, by Employer

| <i>Length of Annual Paid Vacation</i> | <i>All Agencies *</i> | <i>State Government</i> | <i>County Government</i> | <i>Municipal Government</i> | <i>Nonofficial</i> |
|---------------------------------------|-----------------------|-------------------------|--------------------------|-----------------------------|--------------------|
| All replies to question | 1,008 | 165 | 168 | 271 | 288 |
| Number | 100.0 | 100.0 | 100.0 | 100.0 | 100.0 |
| Per cent | | | | | |
| Per cent with paid vacations | 97.2 | 97.0 | 99.4 | 95.6 | 97.9 |
| One week | 2.5 | 1.2 | 3.6 | 2.2 | 2.4 |
| Two weeks | 39.5 | 52.8 | 63.0 | 45.7 | 13.9 |
| Three weeks | 8.4 | 16.4 | 9.5 | 6.3 | 6.3 |
| Four weeks or one month | 33.9 | 13.9 | 13.1 | 24.0 | 65.9 |
| Over one month | 6.6 | 2.4 | 5.4 | 10.0 | 5.9 |
| Other period | 6.3 | 10.3 | 4.8 | 7.4 | 3.5 |
| Per cent with no paid vacation | 2.8 | 3.0 | 0.6 | 4.4 | 2.1 |

* Includes data for nurses who did not indicate their employer and for employees of the federal government, who receive 5 weeks (26 working days) of vacation annually.

agencies also reported vacations of at least 4 weeks. Employees of state and local governments (county and municipal) typically receive 2 weeks of vacation annually (Table 3).

Over half of the public health nurses receive 2 weeks of sick leave annually and one-tenth are allowed 1 week. The amount of leave allowed other nurses varies from less than 1 week to 3 weeks or more after a year's service. Sick leave is less frequent and the period allowed is shorter on the Pacific Coast than in the country as a whole. Most liberal sick leave provisions are reported by federal employees, who are permitted 15 work days of such leave each year.

RETIREMENT, INSURANCE AND MEDICAL CARE

Although provisions for retirement pensions are more common in public health than in all other nursing fields except industrial nursing, about three-fifths of the public health nurses are not covered by retirement pensions contributed to by their employers. Lack of provision for retirement and employment security was the leading source of complaint among public health nurses. Among the nurses covered by a retirement plan were all federal government employees and about half the nurses working for nonofficial and municipal agencies. However, only two-fifths of the state and less than 1 in 3 county nurses benefited from provisions for retirement pensions.

About 7 per cent of the nurses reported accident and health insurance and 8 per cent reported life insurance paid for at least in part by their employers. Such insurance was reported by relatively more employees of nonofficial organizations than of other types of public health agencies.

Provision of hospitalization and medical care paid for wholly or in part by their employers is less common for

public health than for other nurses; only 1 out of 6 members of this field reported such arrangements. Among those who receive any benefits of this sort, periodic physical examinations are most common, reported by 1 nurse out of 8. Nonofficial agencies provide such medical benefits more frequently than official agencies; 1 in 3 nurses working for these private organizations reported hospitalization, medical care or physical examinations or a combination of such benefits.

ATTITUDES

Public health nurses expressed less dissatisfaction with their work than nurse educators, private duty or institutional nurses, and were about as satisfied as industrial and office nurses. Their dissatisfaction was largely concentrated on 4 economic aspects of their work—lack of provision for retirement and security against unemployment, rate of pay, provisions for promotions and pay increases, and opportunities for promotions. These were also the leading sources of dissatisfaction in other fields of nursing. About 1 out of 3 public health nurses expressed dissatisfaction with each of these provisions, and they were more dissatisfied with their pay than were nurses in any other field except institutional work. One in 5 also criticised methods of settling grievances and making suggestions for changes in procedures (Table 4). Among the other aspects of their work considered individually, less than 1 out of 5 public health nurses expressed dissatisfaction; in most cases the proportion of dissatisfied replies did not exceed 1 in 10.

Federal employees were generally more satisfied; and those employed by county and municipal governments were less satisfied than other public health nurses. In summary, agency field nurses expressed the most dissatisfaction and school nurses the least.

TABLE 4

Opinions of Public Health Nurses Regarding Their Work

| Item | Per cent of Nurses Expressing | | |
|---|-------------------------------|--------------|--------------|
| | Dissatisfaction | Satisfaction | No Opinion * |
| Retirement and employment security | 37.5% | 43.6% | 18.9% |
| Methods of determining promotions and pay increases | 33.1 | 39.6 | 27.3 |
| Hourly rate of pay | 31.6 | 35.2 | 33.2 |
| Opportunities for promotion | 28.2 | 37.1 | 34.7 |
| Procedures for settling grievances and suggesting changes in procedures | 19.8 | 51.5 | 28.7 |
| Nonprofessional help | 16.7 | 29.9 | 53.4 |
| Quality of supervision | 15.2 | 55.5 | 29.3 |
| Educational opportunities | 14.6 | 61.8 | 23.6 |

| Advance notice of hours schedule | 2.0 | 34.3 | 63.7 |
| Split shifts | 1.4 | 2.2 | 96.4 |
| Requirement of night-shift work | 1.2 | 3.5 | 95.3 |

Total number of replies — 1,249

* Includes those to whom the item did not apply as well as those expressing no opinion.

SHORTAGE OF NURSING CARE

How do the salaries and other working conditions in public health and other fields of nursing affect the failure of the supply of nursing care to keep pace with increased demands? Available information indicates that these factors affect the supply of nursing care primarily because they do not attract potential student nurses. At present many such students apparently believe that office or factory work offers in comparison more attractive salaries and working conditions than those afforded by the nursing profession, especially when allowance is made for the fact that these other fields do not require the extensive training needed

by professional nurses. Reference to available data suggests that in terms of economic reward nursing may compare unfavorably with some other important categories of employment open to women. This points to an obvious remedy for the shortage of nurses.

Personnel Administration in Public Health*

ALBERT H. ARONSON

*Chief, State Technical Advisory Service, Federal Security Agency,
Washington, D. C.†*

PERSONNEL administration may be defined as the application of formal management techniques to the human relations problems of an organization. Obviously, the necessity for formalized techniques is open to question in any field. Are such techniques the result of sound experience and scientific validation, or are they the ritualistic procedures and mystifying jargon of the professional red-taper? Do they simplify or complicate the performance of the primary job for which the organization is established?

We cannot dodge the human problems in any agency. Personnel activities go on whether we have formalized techniques or not. Any organization, even the smallest, has problems of hiring staff, setting their pay rates, training and supervising them, establishing their hours and working conditions, making judgments as to their performance, discharging or promoting them. Whether an agency needs personnel administration in a formal sense varies with its size and character. It is important that the decision as to the use of personnel procedures and techniques be made after consideration of the experience of other organizations,

rather than in ignorance of such experience. The experience of both public and business organizations should be examined and the successes and failures considered by any public health department before it decides on the kind of personnel set-up adapted to its needs.

While the basic problems of staff management are the same in government and in industry, one additional consideration, not present in private industry, enters into the determination in a public agency as to whether to apply personnel administration as distinguished from personal administration. Even in the same activity, there is some difference between administration in an organization that is the private property of those who direct it, and a public agency, owned by the citizenry at large. An implication of political democracy is the right of people to scrutinize administrative processes. This affects such administrative processes as selection. For example, the public in a democracy regards it as a right of a citizen to be considered for a career in public employment on the basis of objective evaluation of his qualifications rather than on the basis of his personal appeal to the administrator. In other words, in addition to utilizing the contribution of personnel administration to more effective management of the organization, which is the primary consideration, a public agency must give incidental consideration to doing this in

* Presented before the Merit System Unit of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 7, 1947.

† The opinions expressed in this statement are those of the writer, and do not necessarily represent the views of the Federal Security Agency.

a way which recognizes citizen concern in a merit system as a nonpartisan and democratic instrument of government.

Whenever we consider the question of formalized administration, we have to consider an aspect of what might be called the polarity between rule and discretion. This is true of formalized personnel procedures as it is true in other areas. If one operates under rules, certain difficulties appear. A system based on binding regulations may be rigid and may tend to become legalistic. On the other hand, without any regulations, action may be unpredictable and administration chaotic. Uncontrolled discretion may be exercised wisely and consistently, or arbitrarily and even venally. There is no easy answer to the dilemma. It is difficult, but not impossible, to have a system that is objective and understandable, yet with sufficient flexibility in administration to meet new problems as they arise. Certainly, the emphasis should be upon realistic and resilient administration rather than upon regulations as such. As I have said on another occasion, the emphasis in a merit system should be on merit rather than on system. However, unless definite personnel rules are promulgated, adequate machinery established, and proper procedures installed, the merit principle may not be put into effect. The necessity for rules and understandable procedures is more important in those aspects of the merit system that deal with public competition for jobs. But effective dealings with employees in an agency also require a clear understanding on their part of the conditions governing employment.

We have to be careful that we do not include, in formal regulations, provisions which fail to contribute to the efficient functioning of the specific agency and which are not necessary from the overall standpoint of a public agency in a democracy. We must find

means of attaining some degree of objectivity in procedures without sacrificing essential flexibility of administration. Experience in the field of personnel administration will help us by holding up horrible examples as well as instances of real contribution to smooth operation.

Personnel administration has grown up as an incident of large scale administration, first in industry and then in government. Contributions to its method come from two major sources: industrial engineering and psychology. When the economic system depended for industrial production largely upon the artisan, with perhaps an apprentice or two, there was little need for personnel administration as such. With the industrial revolution and the development of large scale industry, management had to become more conscious of its problems in planning, organizing, and coordinating its activities. The human relations aspects of the work situation could no longer be handled in the same way as when the master craftsman and his apprentice worked side by side. Problems of selection, supervision, training, and labor relations emerged. The high paid vice-president in charge of personnel is an illustration of the value that big business sets on increased production through improved human engineering. The management techniques developed by the industrial engineer are illustrated in the personnel field by such developments as job analyses and systems of job classification, by salary surveys and pay scales set on recognized bases. Many of these techniques are applicable in public agencies.

There is another source from which techniques used in modern personnel administration stem—the research of the psychologist, particularly the psychometricians. Human nature is almost countlessly permuted in its variability from person to person. Acceptance of the con-

cept of the range and quantifiability of individual differences is relatively new. The methods of defining and measuring these differences are still newer. Scientific research has established the fact that individual differences can often be measured by methods that do not seem valid on their face. This is comparable to measuring body temperature by something that at first glance seems wholly unrelated—a column of mercury in a glass tube.

Even though we all cherish, to some extent, the notion that we are good judges of people, the utilization of scientific techniques in selection has been so well demonstrated, both in industry and in government, that its value is not seriously questioned even by those who oppose its use on the grounds of feasibility in a given situation. It should be noted that there is a tendency to underestimate rather than to overestimate the differences in the capacity of individuals engaged in a given operation. We sometimes tend to speak of education and experience as though all persons exposed to the same education and experience were of relatively equal competence. In practice, we do not actually accept this, but sometimes we draw up qualifications statements that seem to imply it. Experience has indicated the very real contribution to selection that the application of modern scientific techniques can make in the field of public health.

In considering the utilization of personnel administration in a large organization, we must recognize that the head of such an organization cannot possibly specialize in these problems. His primary task is the application of content in his own professional field; and in a field such as public health, where the boundaries are constantly expanding, keeping abreast of professional developments is itself a most difficult task. It has been said that doctors make poor administrators. I do not believe that

this is necessarily so; there are numerous instances of outstanding professional administrators. However, concentration on professional content may tend to make one ignore or minimize the administrative aspects of his job. Moreover, in the professions there is an individualistic tradition which fosters perfectionism. In medicine the doctor usually starts out as an individual practitioner. It is difficult for someone brought up in that tradition to delegate important responsibility.

The administrator in a professional field must give important attention to administrative management, as well as to professional content. As part of this concern with administration, he must find some way of divesting himself of details in personnel as well as in other administrative areas. Nevertheless, every administrator must concern himself with the handling of men in his organization. He should, therefore, set basic personnel policies but avail himself of technical assistance in their development and application. This implies having a personnel officer, though not necessarily a full-time one. A word of caution might be added here: there is no particular virtue in setting up a job of personnel officer if it is not filled by someone of real competence. The selective process is critical; one cannot identify merely by training or experience those who have a real contribution to make. The public health field has no monopoly on incompetence. There are persons in the personnel field, as well as in other fields, who are lacking either in technical knowledge or intelligence or in the personal attributes necessary in a human relations job. Those dealing with personnel problems require not only a high intelligence and knowledge of the field, but also sensitivity to the reactions of others, freedom from bias, and flexibility in individual and social situations.

Assuming that a public health department obtains a qualified personnel

officer, just what will he do? I will not attempt to detail all the activities of the personnel office but will deal with some illustratively.

An essential to efficient management is analysis of each job to be done and its definition in terms understandable to the worker and useful for other personnel processes such as selection and training. The classification of jobs on the basis of their duties and responsibilities simplifies many phases of administration. The process has important administrative implications in avoiding overlapping or gaps in responsibility. However, job classification must not become an end in itself or become shrouded in specialized terminology. Participation of the administrative officials of the agency and of the employees of the agency is necessary in classification even if it is done by a civil service agency or outside consultants. Similarly, the collection and analysis of data as a basis for establishing pay plans should be approached in a simple and straightforward fashion. A pay plan must not only be based upon some equitable principle, such as paying like rates for like jobs, but must provide for recognition of superior individual performance. This is done through a plan for periodic salary advancement based upon considerations of seniority and efficiency.

Employee training is sometimes neglected in an agency which is too small to have a full-time training officer. Since training is essentially part of effective supervision, every agency can and should have a training program. The role of the personnel or training officer is essentially that of stimulating and facilitating the development of a coordinated program rather than the giving of training courses. However, certain types of induction training, involving the introduction of the employee to the organization and giving him basic information about its structure and

regulations, may be the direct responsibility of the personnel officer. Various types of technical training on the job should be given by the best available specialists. The program as a whole should be planned to permit employees who come in on the lower rungs of a career ladder to rise as they become fitted to assume greater responsibilities. Liaison with educational institutions and the development of a policy for educational leave are related activities. The preparation of employee handbooks is another common function of the personnel office.

The personnel office should also be concerned with services to employees in relation to their individual problems, an activity sometimes called counselling. In any organization there is a wide range of individual problems from that of housing of employees in a community new to them to more intimate personal problems. Employees may have financial or domestic troubles affecting their work which they would be loath to discuss with their supervisors but on which they would welcome sympathetic and understanding help outside the line of supervision. Other personnel activities include employee relations, both with unions or other organized groups, and in connection with individual grievances. The establishment of a suggestion system has been found worth while in some organizations.

The process of evaluating employee performance is an inescapable one. One talks in the personnel field about service ratings as a formal method of recording periodic judgments. We must not let jargon obscure the fact that we are recording opinion. The administrator must decide whether it is better to do this systematically or informally as the need arises for a judgment. There is evidence to support the view that a system of service ratings, based upon standards of job performance, will improve the process of judgment and

supervision, but it is important to note that these performance standards must be developed within the organization. If a service rating form and procedures are transplanted from one state to another, without considering whether they are needed and wanted by supervisors and staff, the result may be red tape and the hampering rather than the simplifying of administration.

Problems of employee placement, separation, and promotion may be facilitated by the personnel office. The functions of such an office include working with the civil service or merit system agency in relation to examinations. Such liaison should help in achieving a planned examination program and in speeding up the examination process. The personnel office may also give assistance in recruiting and utilization of professional consultants by the civil service agency.

I do not propose to discuss the subject of civil service at any length, but it should be noted that the civil service field furnishes an admirable example of our American tendency to regard problems as solved when laws are passed. There have been several waves of civil service reform, bringing with them statutory establishment of formal systems. Some of these are well administered; some are poorly administered. The existence of a civil service system is no guarantee that it is better than a spoils system. Inevitably the best civil service system brings with it a certain amount of rigidity. How much of this is necessary is debatable, and how much is a reasonable price for freedom from worse alternatives is also debatable. It has been said that the only thing worse than civil service is no civil service. I do not believe that we have to accept a rigid system that does not in point of fact produce results commensurate with the time and effort involved. In order to achieve such results, it is essential that persons engaged

in various professional fields such as public health play a continuing and energetic role in the administration of the system. They must understand it; they must criticize it.

It is well to remember that it is the operation of the system that we must evaluate and not merely its framework. The best examination is of no value if it is so long drawn out that competent candidates are lost in the process. The most elaborate administration of a compensation plan is valueless if the basic pay rates are such that competent persons cannot be recruited and retained. The implications of this for the public health field are clear. Professional personnel must be utilized at various places in the merit system process—in recruitment, consultation on examinations, and evaluation of results. Within agencies, supervisory staff and professional personnel must be concerned with personnel practices, including the development of performance standards as a basis for rating employees, the establishment of realistic qualifications that will broaden the recruitment base and permit the selection of the best available persons, and the establishment of working conditions that will promote efficiency and job satisfaction.

It must be recognized that the techniques of personnel administration, even though of proved value, are no substitute for administrative leadership. The head of any organization must have interest in staff problems, courage, and perspective, as well as professional competence. Personnel administration may aid the good administrator, but it cannot take his place.

It has often been said that formal merit systems prevent the discharge of employees. This is true in some cases, but, basically, discharging anyone is an unpleasant job. All of us know of educational institutions and business organizations where deadwood is tolerated because of inertia or the unwillingness

of executives to take needed action and stand up under pressure. If a personnel system is so tied up with red tape that it is impossible to discharge the incompetent, there is something wrong with the system. We should not accept something that is called a merit system and stop there. There are systems that impede good administration, and there are some that are definitely aids to good administration. Within any jurisdiction, one must critically examine the functioning of the system and vigorously support its sound features, and just as vigorously support necessary change.

In a scientific field, open-mindedness is clearly a condition of progress. Yet it is a curious thing that, outside their own fields, scientists may permit their unexamined prejudices to govern their actions. The attitude of administrators in the public health field toward personnel administration should be open-minded but not naive. One who looks to personnel administration as a panacea for administrative ills is doomed to disappointment. Unquestioned acceptance is as bad as defeatist cynicism. Properly applied, the techniques of personnel administration can contribute to the solution of management problems but will not prevent those problems from recurring. Improperly applied, the same techniques can be a source of continuing frustration to the administrator.

In a governmental organization, we do not have a criterion of profit to determine success or failure. Nevertheless, evaluation of accomplishment is imperative. The criterion of public service is the substitute for the criterion of profit. I sometimes think that we do not recognize that there is as much of a difference in efficiency between the best administration and the poorest administration of a governmental or-

ganization as there is between a firm that makes a handsome profit and one that goes bankrupt because of inefficiency. There are public agencies that should file petitions of bankruptcy, and there are others that are entitled to stand upon their records. We tend to blanket them all together as bureaucracy. Before the public and legislatures can make a valid differentiation, administrators themselves must be prepared to recognize the differences and evaluate the causes.

I do not mean to imply that a total program should be evaluated on the basis of its personnel administration. An agency may have a poor personnel program and a good health program, or it may have a good personnel program and a poor health program. Nevertheless, if one examines the proportion of the budget of any health department that is spent for personal services, the critical importance of personnel administration will be apparent. It will be agreed that the human element looms large and that the job satisfaction and the efficiency with which the individuals are performing their work are important factors in the success or failure of the program.

At the same time that we keep in view the primary goals of the organization and assure adequate attention to professional content, we must include within our perspective the techniques of administrative management. Personnel administration, of course, will not solve the human relations problems of any organization, but it should promote more effective management and hence promote the accomplishment of the primary goals of the organization. Effective personnel administration has a modest but nevertheless significant contribution to make in attaining the goal of effective public service.

Factors of Sewage Pollution of Oyster Beds in Galveston Bay*

ROBERT I. WISE, PH.D., JOE B. WINSTON, B.S., AND
GEORGE CULLI, JR.

Director of Bacteriology and Serology Laboratories, John Sealy Hospital, School of Medicine, University of Texas, Galveston, Tex.; Sanitary Engineer, Sigler, Clark & Winston, Consulting Engineers, Weslaco, Tex., Formerly Associate Professor, Department of Preventive Medicine and Public Health, School of Medicine, University of Texas, Galveston, Tex.; Supervisor of Shellfish Sanitation, Division of Engineering, The Texas State Health Department, Austin, Tex.

IN February, 1944, an outbreak of food poisoning occurred in Galveston as the apparent result of eating raw oysters at a fraternity banquet. No samples were available for laboratory examination; however, the exact meal was easily determined in that several guests and members who were ill ate all other meals at their homes. Epidemiological evidence showed conclusively that raw oysters were the cause of the outbreak, and all other foods served were eliminated. These facts have been reported by Wise, Winston, and Nau¹ in an earlier publication. A thorough bacteriological study of oyster beds in Galveston Bay, where the oysters had been collected, was instigated to determine the sanitary conditions of the oyster beds and to study various factors which might influence sanitary quality.

It has long been known that oysters may carry pathogenic bacteria. Many cases of typhoid fever and gastrointestinal disturbances have been attributed to oysters and other shellfish. In 1818,

several decades before the discovery of microorganisms as the cause of infectious diseases, Pasquier² concluded that cases of gastrointestinal illness resulted from the eating of raw oysters collected in sewage polluted waters. Johnston-Travis³ in 1895 attributed cases of typhoid fever and enteritis in Naples and Rome to oysters which had been dredged from clean waters and kept for a period of days or months in water near a sewage drain. In Brighton, England, the cases of enteric fever ascribed yearly to oysters by News-holme⁴ were 21 in 1894, 19 in 1895, 31 in 1896, 30 in 1897, 41 in 1898, 52 in 1899, 17 in 1900, 9 in 1901, and 21 in 1902.

An epidemic of typhoid fever occurred at Wesleyan University in Middletown, Conn., in 1894, and was reported by Conn.⁵ Thirty cases were involved, and 4 deaths occurred. All had eaten at a fraternity supper where raw oysters had been served. In an excellent epidemiological investigation it was found that the oysters had been obtained from a fisherman who kept them in a river near his sewer outlet. The fisherman's wife had died of typhoid fever and his daughter was ill with the same disease.

* This study was made at the Medical Branch of the University of Texas when Robert I. Wise was Assistant Professor in the Department of Bacteriology and Joe B. Winston was Associate Professor in the Department of Preventive Medicine and Public Health.

Broadbent⁶ in 1895 reported 11 cases of typhoid fever caused by eating oysters. Thresh and Wood⁷ in 1902 reported cases of typhoid fever and gastroenteritis caused by oysters bought from one dealer. Evidence collected by Marvel⁸ in 1902 pointed to oysters as the source of many cases of typhoid fever in Atlantic City. The oysters were being "fattened" in water polluted by sewage from the city.⁹

An outbreak of 50 cases of typhoid fever was described by Brooks¹⁰ in 1916. These cases occurred in 6 municipalities in New York State, in 3 of which there had been no cases in over 10 months and in one none in 5 months. There was apparently no possible common source of infection other than oysters purchased from various dealers.

Extensive outbreaks of typhoid fever occurred in Chicago and New York at the same time in 1925. Reports were made by Bundesen¹¹ and Harris.¹² In Chicago 129 cases involving 16 deaths occurred in 52 days. All foods except oysters were excluded as the probable cause. The oyster plant which had supplied the oysters was located on Long Island and found to be in excellent sanitary condition. Oysters had been received from beds where two fishermen were employed. These men had typhoid fever, and each day during the incubation period of their illness, they had worked over the oyster beds and, having no toilet facilities on the boat, their discharges were dumped overboard on to the oyster beds. A large sewer line was also found to be emptying approximately 100,000,000 gal. of sewage into a nearby area. In the New York epidemic there were 914 cases of typhoid fever, of which 506 gave a definite history of eating oysters as the only likely source of infection. The water supply, milk, ice cream, ice, and vegetables were eliminated as a source of infection.

Extensive bacteriological studies of

oyster beds have been made along the Atlantic Coast of the United States. Narragansett Bay was studied by Fuller¹³ in 1902 at which time the City of Providence, R. I., was discharging daily about 14,000,000 gal. of sewage into the bay. Studies showed that water and all oysters within 2 miles from the sewer opening showed coliform organisms; 30 per cent of oysters and 60 per cent of water samples 5 miles from the sewer showed coliform organisms.

Johnston¹⁴ studied the effect of the tide on evidences of sewage pollution in water above oyster beds. He found the number of coliform organisms to decrease during flood tide and increase significantly during ebb tide. These results demonstrate the variation in results one may obtain by making only one test or paying little attention to conditions which may influence the laboratory results.

Several investigators have observed a definite relation between the temperature of water and coliform content of the oysters. Gorham,¹⁵ Joseph,¹⁶ and Gage and Gorham¹⁷ demonstrated that in waters along the northern Atlantic Coast of the United States the bacterial content of oysters in polluted water at low temperatures is abnormally low. As soon as the temperature of the water began to increase, the coliform content of the oysters increased to a high count which was held throughout the summer and decreased in the fall. This phenomenon was attributed to the slowing down of physiological activity of the oysters as a result of decreasing temperature. Observations on the physiology of oysters at various temperatures were made by Galtsoff.¹⁸ The rate of flow of water produced by the gills of the oysters is controlled by the temperature. No current is produced at 5°C. and below, and the oyster remains closed and in a state of hibernation. Bacteria are eliminated. The

water flow in the oyster begins as the temperature reaches 8°C. The optimum temperature for maximum water flow was reported by Galtsoff to be between 25° and 30°C., at which temperature the maximum rate of flow was 3.9 liters per hour. Cumming,¹⁹ studying the sanitary conditions of shellfish in the lower Potomac River, found that January and February were the months when the coliform content of water at the mouth of the river was highest and the coliform content of the oysters from the same locality was lowest.

THE PRESENT INVESTIGATION

It was the purpose of this investigation to (1) learn some of the important facts concerning sewage pollution of oyster beds and the water over the beds, (2) to follow the changes in pollution by frequent sampling over a period of time, (3) to study the effect of external factors on sanitary conditions, and (4) to determine whether or not conclusions based on similar studies made along the North Atlantic Coast of the United States are applicable for conditions in the Gulf Coast area.

Hopkins²⁰ has pointed out differences in oyster culture in waters of the Gulf Coast and those of the North Atlantic Coast even though the oysters are of the same species (*Ostrea virginica*). Oyster reefs on the Gulf Coast are usually found in shallow water no more than 2 to 8 feet below low water level, whereas, in northern waters, oyster beds may be under much deeper water. The shallow bays of the Gulf Coast are more readily affected by rains and changes in temperature. The spawning season of oysters in southern waters is long as compared to a short season in northern waters. It is known that in northern waters low temperatures are reached and the oysters enter a state of hibernation. Water temperatures reported necessary for hibernation

and cessation of water flow and feeding in the oyster in northern waters are rarely reached in Gulf Coast waters. According to Gunter²¹ oysters of the Gulf Coast do not hibernate, but feed and grow mainly during the winter and are fattest in the late winter and early spring.

Galveston Bay and its oyster reefs have been described by Galtsoff.²² The bay extends 24 miles from its entrance at Galveston Island to Morgan's Point at the mouth of San Jacinto Bay. It has an average depth of 7 feet. Its branches are East Bay, which is separated from Galveston Bay by an oyster reef (Hanna Reef), Trinity Bay on the north, and West Bay on the south. Red Fish Bar is a chain of oyster reefs extending from Edwards Point to Smith Point, and divides Galveston Bay into southern and northern parts. Three major watersheds discharge fresh water into Galveston Bay. The Buffalo Bayou watershed collects water from the Houston area and serves as the Houston ship channel. Buffalo Bayou watershed is 75 miles long and is 1,065 sq. mi. in drainage area. It enters Galveston Bay through San Jacinto Bay at Morgan's Point. San Jacinto River watershed serves a drainage area 3,018 sq. mi. in area and heads 140 mi. from its entrance to Galveston Bay at San Jacinto Bay. Trinity River serves a large area, 17,600 sq. mi. in drainage area, and heads 360 mi. from its mouth at the northern part of Galveston Bay.

Three oyster reefs in Galveston Bay are used for commercial harvesting. The locations of Hanna Reef and Red Fish Bar are mentioned above. Half-Moon Reef was the third reef studied in this investigation and is located approximately 1 mi. east of Texas City and north of the Texas City dike.

Untreated and partially treated sewage enters Galveston Bay from several sources. Houston, during the year of

this investigation, was discharging untreated and partially treated sewage into Buffalo Bayou. Texas City discharged daily approximately 500,000 gal. of domestic sewage directly into Galveston Bay south of the dike, and the city of Galveston discharged approximately 12,000,000 gal. of sewage daily into the harbor north of the city between Galveston and Pelican Islands. Smaller communities around the bay and located on Buffalo Bayou and Trinity River contributed to the pollution.

METHOD OF STUDY

Five water samples were collected from each reef every month from March, 1944, through January, 1945, with the exception of the months of April, May, and June, 1944. Oyster samples were collected from each reef every month from July, 1944, to January, 1945.

Both the total coliform content and the *Escherichia coli* content were determined on all water and oyster samples using the procedures of *Standard Methods for the Examination of Water and Sewage*²³ to determine the most probable number per 100 ml. of sample by inoculating 5 portions in each of 3 dilutions in geometric series in tubes of lactose broth, streaking to E.M.B. agar and transferring typical coliform colonies to lactose broth and citrate agar. The oysters were prepared and studied according to *Recommended*

Procedures for Bacteriological Examination of Shellfish and Shellfish Waters.²⁴ Koser's citrate broth was used to differentiate *E. coli* from other coliform organisms.

Measurements for salinity and turbidity were made on each sample of water. Water and air temperatures were recorded at the time of collection.

RESULTS

The coliform content of the water (Table 1, Figure 1) was found to be greatest in late winter and early spring. The two reefs, Red Fish and Half Moon, which are close to sources of pollution, showed a decrease during summer months. The coliform content of water over Red Fish and Half Moon Reefs decreased from 947 and 852 respectively in March, to less than 10 for Red Fish and less than 30 for Half Moon in July. These lower values were held through the summer and fall. In January the coliform content increased to 482 for Red Fish and 378 for Half Moon. Hanna Reef which is not near the ship channels and less subject to currents which would accumulate sewage, showed least evidence of pollution; the highest coliform content found was 11 in March.

The coliform content of the oysters (Table 2, Figure 1) in general follow the same course as that of the water. The coliform contents of oysters in July were Red Fish 49, Half Moon 100, and Hanna 49. Red Fish and Hanna

FIGURE 1—Mean Coliform Contents of Oysters and Water over the Oyster Beds from March, 1944, to January, 1945

TABLE 2

Coliform Content of Oysters
Most Probable Number per 100 ml.

| | July | Aug. | Sept. | Oct. | Nov. | Dec. | Jan. |
|-----------|------|------|-------|------|------|------|-------|
| Red Fish | 49 | 2 | 2 | 0 | 6.8 | 4.5 | 1,600 |
| Half Moon | 170 | 17 | 22 | 45 | 13 | 110 | 240 |
| Hanna | 49 | 0 | 2 | 0 | 2 | 6.8 | 23 |

showed decreases to numbers less than 10. Half Moon fluctuated between 13 and 45 from August to November. Half Moon showed an increase to 110 in December and 240 in January. Red Fish showed the highest coliform content observed in January when an increase to more than 1,600 occurred.

The oysters show greater numbers of

coliform organisms per 100 ml. than does the water, as is shown in Figure 1. Little information is gained by calculating the ratios of coliform contents of the water to those for the oysters. Ratios vary from 0.008 to 2.7 and do not correlate with temperature, season, or any other factor studied.

The turbidity of the water was found

to be high (400-550 p.p.m.) in late winter and fell to approximately 50 p.p.m. in July, a value held until December. In January turbidity increased to 110-215 p.p.m. All reefs showed approximately the same fluctuations in turbidity during the year.

Salinity of the water was low during the winter months and higher during summer and fall. Half Moon Reef being nearest the Gulf showed naturally

the greatest salinity and Red Fish Reef the lowest, since it is nearest the mouth of Buffalo Bayou and Trinity River. Since Half Moon Reef showed greater evidence of pollution than Red Fish Reef, it can be concluded that cities discharging domestic sewage near the Gulf end of the bay contribute to the pollution of the oysters in the bay, in that sewage is carried into the bay by tidal currents; otherwise Red Fish Reef

FIGURE 2—Relationship of *E. coli* to Total Coliform Water Samples over Oyster Beds in Galveston Bay in Comparison with Total Stream Flow into Galveston Bay during the Same Season

* This relationship is represented by the formula $100-100 \left(\frac{\text{MPN } E. coli}{\text{MPN coliform}} \right)$. Only water samples containing more than 2 coliform organisms per 100 ml. were used in the calculation.

FIGURE 3

would show greater evidence of pollution than Half Moon Reef since all the fresh water entering Galveston Bay from the Trinity River and Buffalo Bayou watersheds crosses Red Fish Reef.

It was observed that during the period of this investigation the temperature of the water never reached the point necessary for hibernation of the oysters and cessation of water flow through the oysters. In the 20 year

period (1922-1942) the lowest mean temperature value for any month was 7.9°C., which occurred in January, 1940. The minimum temperature fell below 5°C., the temperature reported by Galtsoff as necessary for cessation of water flow, during the years 1924 (4°C.) 1940, (1.5°C.), and 1942 (4.5°C.). It can be concluded that oysters in the Gulf Coast area rarely reach the low temperature at which water flow ceases and bacterial flora is decreased as reported by investigators who have made similar studies in North Atlantic waters.

A comparison of Figures 1 and 2 shows that the coliform contents of the water and oysters during the year vary directly with the stream flow into Galveston Bay. They vary inversely with the temperature of the air and water. It is natural that salinity varied inversely and turbidity varied directly with degree of pollution, since these factors are dependent on stream flow.

It is evident that a high coliform count in the water and oysters occurred concurrently with an increased flow of fresh water into the bay during the winter and spring seasons. The coliform content of the oysters increased as the temperature of the water decreased, and was highest during the latter part of the "oyster season." These findings are in contrast to the reports of Gorham^{15, 17} and Joseph,¹⁶ who reported higher coliform counts during the summer and lower counts during the winter.

Figure 2 shows the relationship of *E. coli* to the total coliform content of the water samples. The ratios of the mean values of *E. coli* to the total coliform content of the samples have been calculated as percentages and subtracted from 100 per cent in order to invert the curve for better comparison with variation in stream flow. It can be observed that as the stream flow was at a minimum during the summer

and fall season, the percentage of *E. coli* among the total coliform group increased. As stream flow into the bay increased in December and January the percentage of *E. coli* decreased.

It is possible that these results may be explained by differences in dilution of sewage by drainage water during various seasons. In winter and spring there is more rainfall and greater dilution of sewage with a decrease in *E. coli* per unit volume of water. In the summer and fall seasons there is less rainfall over the drainage area and the decreased dilution of sewage results in an increased percentage of *E. coli* in the total coliform group per unit volume of water.

SUMMARY

The changes in coliform content of oysters and water above the oyster reefs in Galveston Bay, Tex., were found to decrease in the spring, remain at low level from July to December, and increase to high values during January. This is in contrast to reports made by investigators who have made similar studies along the North Atlantic Coast and report a decrease in coliform organisms as the temperature of the water falls.

On the Gulf Coast the temperature of the water rarely decreases to a point necessary to cause hibernation of the oyster and cessation of water flow, thus the oysters do not show a decrease in coliform content when harvested from polluted waters during the usual winter temperatures, as has been reported for oysters of the North Atlantic Coast.

Oysters usually showed greater pollution than the water, however, ratios of coliform contents of water to oysters did not correlate with other factors studied and were of no informative value.

The total volume of water entering the bay each month correlated with the degree of pollution. Salinity varied in-

versely with the volume of water entering the area and inversely with the coliform content. Turbidity of the water varied directly with the water volume and directly with the coliform content.

The percentage of *E. coli* to total coliform flora in the water over the oyster beds increased from July to November as stream flow was minimal. The percentage decreased markedly in December and January as stream flow into Galveston Bay increased.

Modified Self-Selection Method of Feeding Preschool Children in the Home*

MARGARET F. GUTELIUS, M.D.

Dysentery Control Project, Pharr, Tex.

THERE are two problems in nutrition which confront the housewife and mother: (1) The adaptation to the home of the modern knowledge of nutritional requirements, and (2) the proper handling of children so that they will take adequate diets. Psychologists have pointed the way to avoiding feeding difficulties, but the practical application of their principles in the home has not been extensively studied or reported upon except for infants.

One basic approach to these problems is the use of free choice in all that pertains to eating. Richter¹ has demonstrated in animals with a specific deficiency the marked ability to select the food factor needed. Davis^{2, 3} has shown that both infants and children in hospitals maintain excellent health and develop no feeding problems when allowed to choose their own meals. These experiments involved offering a wide variety of foodstuffs, the use primarily of natural foods, and the avoidance of any psychological barriers to the enjoyment of meals.

A similar freedom in eating is recommended by many pediatricians for the home.⁴ For infants this method has received wide attention and acceptance.⁵⁻⁷ Babies on a self-demand schedule grow normally and quickly form regular hab-

its. A choice of formulas need not be offered since infants show no marked preferences.⁸ This regime offers few difficulties for the parents.

Free choice for preschool children at home has not received the same study and presents certain problems.

1. The preparation of meals at irregular hours or of a wide variety of foods for each meal is seldom possible.

2. The extensive use of highly demineralized and devitaminized foods, especially sugar and white flour products, probably limits the freedom of choice which one can safely allow. In some homes it may even be impossible for self-selection to result in an adequate diet. Moreover, even when the home diet is good, children are over-stimulated to take the above foods because in our civilization they are for sale on every street corner.

3. It is more difficult for a parent than for a supervisor in an institutional experiment to avoid concern over what and how a child eats.

4. Finally, the example set by parents at meals is important.

The experiences reported here took place in a home where both parents are physicians. The two girls are at present 6 and 4 years old. The elder, F., was about 18 months of age when the free-choice method of feeding was undertaken. As an infant she had not been kept to a rigid schedule or forced to eat. On the other hand, desire to eat had not been given prime importance in planning her schedule. Furthermore, this parent worried considerably over food intake. Games and tricks were tried to encourage her to eat, but without success. She seemed to be con-

* Presented before the Maternal and Child Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

suming very little and was taking an hour for a meal when the change in parental attitude began. Despite the fact that both parents accepted the logic of the new regime to which they had given some study, there was a certain amount of emotional difficulty in changing to a policy of *laissez faire*.

The younger child, S., was allowed from birth to choose the time for her feedings, the quantity, and later the type of food she desired. She always had a good appetite. By 15 months of age she was feeding herself without help. She was able to use a spoon correctly and took a large part of her liquids from a cup.

MODIFIED SELF-SELECTION METHOD

When F. was 18 months of age the following method of feeding was begun and has continued to date. S. was put on the same regime when she reached 15 months. At the time of starting, both children were eating without help from an adult.

Three meals a day are prepared at regular hours unless the children ask to eat early and it is convenient for them to do so. They are usually fed by themselves in the kitchen before the parents eat. The table is set attractively. Only small portions of each food are put on their plates. The mother remains with them giving her attention to other work, but ready to help them if they ask for it.

The children are allowed almost complete freedom in what they eat and how they eat it. They may ask for food not on the table or take nothing at all. When they ask for something which is not convenient to prepare or which is not in the house, they are promised the food at the earliest possible date. They are allowed any quantity of the foods available (with the exceptions noted below), any variety, and all the time they want for eating. They may eat with their fingers, drink from a bowl, sing. They may play while eating, play with the food, or take

it outdoors to eat. They do for themselves as much as they wish.

The adult present makes no comments and shows no concern over the foods chosen or the quantity eaten. Accidents are cleaned up calmly and the child often helps. The children are advised not to take or ask for more food then they feel they can eat. Table manners are not mentioned until the child shows an interest in the matter.

In addition to three meals daily there are always available certain ready-to-eat and non-messy foods that the child can get at any time of day. Also the parent, if not busy, gets any easily prepared food when the child asks for it.

There are some rules for behavior and these are enforced: (1) Only certain places are used for eating. (2) Food is not to be thrown about or wantonly made unfit to eat. (3) The children are not to annoy their parents when the latter are eating.

The meals consist of simple foods easily prepared. For breakfast, eggs in various styles, any of some dozen cereals, and several fruits are offered. Lunch and supper are much alike. Besides numerous fruits and vegetables (usually raw), there is a choice of at least two meats. As a rule only one meat requires cooking, the other being served cold from a previously used roast, ham, or fowl. Milk and bread are offered for each meal, and another concentrated carbohydrate besides the bread. A limited amount of one of the foods commonly called "dessert" is set out with the rest of the meal or when requested. Dishes requiring long preparation are rarely used. The usual meal is prepared and consumed in 20-40 minutes. Exceptions occur when oven-cooked foods are served or a food jag appears. In the latter case repeated orders have to be filled.

In the early months a fairly wide variety of choices was served, but after the children learned to talk well, it be-

| | Salmon, 2 tablespoons (canned, opened for cat) |
| | Celery, ½ stalk |
| | Okra, 2 whole, raw |
| | Ice Cream, homemade, 2 tablespoons |
| 8.00 P.M. | Apple juice, 6 oz. helped self |

came possible to display less and to ask what they wanted from the foods available. They are not pressed for a decision and some variety on the table is found to stimulate their interest.

The foods offered the children are for the most part natural products, and an effort is made to help them like this type of diet by having such foods easily available at all times. For example, various kinds of fresh fruit are always in a bowl on their table. Some raw vegetables are kept in the refrigerator where they can be reached when wanted. These may include carrots, celery, cabbage, cucumbers, lettuce, string beans, green peppers, turnips, cauliflower, okra, and peas. Only artichokes, beets and corn are routinely cooked. The provision of a wide variety is easy under these conditions and there is the added advantage of preserving minerals and vitamins.

The devitalized foods, especially sweets and articles made of white flour, are avoided as much as possible. Whole grain products including brown rice are used almost entirely. Muffins, pancakes,

gravies, etc., are made with whole wheat flour. Honey and syrups are always on hand. These, along with brown sugar, are used in cooking and on unsweetened cereals. Fancy baked goods and desserts are rarely bought or made. The same is true for jams, jellies, and soft drinks. A favorite hot weather drink is "sweetnin' water" which is cane syrup in water.

Only occasionally has it been found necessary to restrict the quantity chosen by the children from products containing white flour. On the other hand, sweets except for honey and syrups, have always been limited to a very definite amount. None are allowed between meals. At lunch and supper there is usually a choice of one cookie, a small piece of candy or ice cream, all of which are homemade. This restriction on sweets is the only curb imposed on free choice other than that made by the type of food habitually bought for the home.

The above regime offers the children the opportunity to take a good diet. The parents are fortunately able to set a good example. They enjoy all foods

TABLE 3
Complete Eating Schedule for One Day

F. Age 6

Breakfast

7:30-7:45 A.M. at kitchen table

Powdered milk, 1 bowl with water (equal to 1 pint whole milk)
Egg, $\frac{1}{2}$, scrambled
Cereal, cooked Ralston, 3 bowls with cream and brown sugar
Bread, whole wheat, 1 slice, with butter
Grapefruit, $\frac{1}{2}$

(Nothing between breakfast and lunch)

Lunch

12:00-12:20 at table

Milk, 4 oz.
Hamburger, 1 medium
Bread, whole wheat, 1 slice, with butter
Cheerioats—2 handfuls
Carrot—1 medium
Candy—1 small
Watermelon, 1 slice, requested help
Raisins, 1 handful, helped self

4:30 P.M. outdoors

Supper

6:00-6:20 P.M. at table

Milk, 5 oz.
Ham, 2 slices
Waffles, 3, with syrup and cream
Okra, 1, raw
Corn, $\frac{1}{2}$ ear, cooked
Peach, 1, fresh
Ice cream, homemade, 1 scoop

and rarely have desserts. It took very little effort for them to like the type of diet desired for the children.

Table 1 gives typical menus with the foods eaten by each child. Tables 2 and 3 show complete eating schedules for one day.

RESULTS

Both children have good appetites and enjoy eating. They are self-reliant and usually eager to help prepare their food by pouring milk, squeezing oranges, scraping carrots, slicing cheese, and putting the scraps in the garbage pail. Between meals they customarily help themselves without bothering an adult. There is very little fussing over the limitation on sweets. Weeks and months go by without any request for extra amounts of these foods.

Table behavior has been unconventional in many respects, but not objectionable. Also the conduct of the children has consistently become more civilized as they grow older. Meals are pleasant occasions. The children usually eat quickly with little dawdling. Occasionally, in the early years, a meal

lasted an hour. Jumping up from the table is still common. Playing with the food is usually confined to afternoon "tea parties." There has always been a minimum of messiness and spilling. Such things as eating with fingers and licking the plate are now infrequent. At about 5 years of age F. became increasingly interested in adult table manners and at present takes great pride when away from home in being polite and in eating all that is set before her without comment. This was done on her own initiative. She is now ready to eat with the rest of the family when she wishes to do so.

The foods chosen by the children show wide variation in type and quantity from day to day, and week to week. For this reason, in order to estimate the composition of their diet, a record was kept of everything eaten and the approximate amounts in household measures over a period of 6 weeks during one winter. F. was 3½ and S. almost 2 years old at the time.

The average daily intake from various food groups during this 6 week period

TABLE 4
Approximate Average Daily Intake

| <i>Food Groups</i> | <i>Measure</i> | <i>F. Age 3½</i> | <i>S. Age 2</i> | <i>Recommended by National Food Guide</i> |
|--|-----------------|------------------|-----------------|---|
| 1. Milk (Cheese, ice cream) | Cup (8 oz.) | 2.4 | 2.1 | 3-4 |
| 2. Meat, fish, fowl (Legumes, nuts) | * Servings | 1.1 | 1.7 | 1-2 |
| 3. Eggs | No. | 0.8 | 0.4 | 4 a week |
| 4. Vegetables Green or Yellow | * Serving | 1.2 | 1.0 | 1 or more |
| 5. Citrus fruit (Other foods high in vitamin C) | * Serving | 3.2 | 3.0 | 1 or more |
| 6. Other fruits and Vegetables | * Serving | 2.1 | 2.6 | 2 or more |
| 7. † Bread or Cereals Whole grain or enriched products | Slices or Bowls | 2.5 | 1.9 | Some |
| 8. Butter or Oleo | Pats (10 gm.) | 1.0 | 0.9 | Some |

* Servings:

Meat —2 oz.
Vegetables—1 med. carrot; ½ head broccoli; ½ cucumber, ¼ head lettuce, 1 small potato, 2 heaping tablespoons cooked vegetables, etc.
Fruit —1 med. orange, pear, peach, banana or apple, 4 oz. fruit juice, 5 figs or prunes, 20 raisins or grapes, etc.

† Includes pancakes, waffles, muffins, brown rice, popcorn.

is shown for each child in Table 4. The food groups have been arranged to conform with the *Basic 7* of the *National Food Guide*,⁹ except that eggs have been taken from the meat group to form an eighth group. The final column shows the recommendations of the *National Food Guide*.

It is seen that both children had an average daily intake of over a pint of milk, more than one serving from the meat group, about half an egg, one serving of green or yellow vegetables, several servings of citrus fruit, two other fruits or vegetables, two servings of a grain product and about a pat of butter or oleo. Not recorded under the milk group was a very small amount of cheese and ice cream. Not recorded under the meat group was a moderate amount of nuts and peanut butter taken by the older child. Almost all of the fruits and vegetables were raw and fresh. All of the bread and over half of the cereals were of the whole grain variety, the rest fortified.

Beside the *Basic 7*, the *National Food Guide* lists certain foods which are chiefly energy giving, and not shown in Table 4. From this group both children took a daily average of about one-half strip of bacon and one teaspoonful of syrup or brown sugar. The older child also had approximately one small cookie and one-third of a piece of candy. Finally, both children received 400 I.U. of vitamin D supplement daily. They were both sun-tanned at this time as they have been the year round since 3 weeks of age—one advantage of living in the South.

The diets taken by the children are entirely satisfactory in comparison with the recommendations of the *National Food Guide* except for milk intake. In this case the 3 to 4 cups suggested as standard is a general allowance for all ages of children, but good authority exists for believing that there is an exception in the early preschool years

when a pint is considered sufficient.^{10, 11} There was some added milk in cooked foods taken by these children, and there are times when they drink considerably more than in the particular 6 week period recorded. For the past 6 months, they have both been taking about 1 quart daily.

The average daily intake of the children does not differ materially from diets for preschool children prepared by Butler¹² and Dann.¹³ These diets are more specific than that of the *National Food Guide* and are designed to meet the daily allowances for various nutrients recommended by the Committee on Food and Nutrition of the National Research Council.¹⁴

The daily intake as tabulated supplied 1,200–1,500 calories. It was high in protein and low in carbohydrate when compared to the usual American diet. The vitamins were abundant.

In addition to taking an adequate diet the children present certain eating habits which are of interest. About one-third of the food is taken between meals but this consists for the most part in fruits, vegetables, and milk. One meal daily is usually much larger than the others but which meal is hearty varies from time to time. The quantity taken on some days may be several times greater than that taken on other days. An enormous appetite may last for weeks to be followed by a sharply reduced intake for no apparent reason.

The children prefer each food by itself and dislike such mixtures as stews, hash, and fancy salads. Even salt is often taken alone especially in hot weather. They have developed a taste for raw foods and whole grain products. There is a large amount of roughage in their diets, but it does not seem to upset them. An occasional loose stool or the presence of undigested food particles in the stool has never been followed by diarrhea. They preferred the "dessert" in the middle of the meal until recently

when they started taking it at the end.

The children tend to limit the variety at any one meal and concentrate on 2 or 3 foods, although this tendency has become less marked as they grow older. The extension of this tendency, the so-called "food jag," is very common, and it may last for days or weeks. There have been jags on almost every well-liked food including numerous fruits and vegetables. On various occasions a meal has consisted of a large amount of a single item, e.g.: 6 eggs, 3 cucumbers, 6 chicken legs, 2 large cans of evaporated milk, 7 bananas, or 8 slices of bread. One child asked for shredded wheat at every meal for several weeks. Watermelon season has been celebrated by having watermelon 6 to 7 times daily for a week. No gastrointestinal upset ever resulted from these jags. In spite of the tendency to concentrate, very few days have passed without there being some choice made from every food group. Especially milk and citrus fruit are rarely skipped entirely. At present about one-half or more of the individual meals are well "balanced." Each child consistently favors certain foods, e.g., one is partial to meats and fruits, the other to eggs and cereals.

The children are not omnivorous eaters, but they take a wide variety of foods which is increasing all the time. They like all fruits; almost all kinds of meat, fish, fowl, cereal; about 15 vegetables. For some reason they have never liked white potatoes except as chips, or cooked greens of any kind. It is interesting to note that even their favorite dishes are refused at times.

Both children have grown and developed normally and show no tooth decay. One is unusually tall, both have always been slender but firm and strong. Table 5 shows the height and weight records. Their growth curves are within normal levels.¹⁵

Both children have had occasional

TABLE 5
Weight—Lbs.—Ozs.

| 4 | 37-8 | 32-0 | 43.0 | 39.0 |
| 5 | 42-0 | | 45.5 | |
| 6 | 46-0 | | 47.7 | |

upper respiratory infections after 1 year of age, but no serious illness. There have been very few and very minor digestive disturbances. Neither child has ever taken or needed a laxative or enema.

DISCUSSION

The success of this method of feeding children presupposes a fundamentally happy home without undue emotional tensions in fields other than eating. It would seem that these tensions may well upset the appetite even when the feeding method itself is sound.

It cannot be assumed that this method will necessarily be successful with a child who has already acquired faulty eating habits. Cure is more difficult than prevention and cannot be discussed here.

The satisfactory operation of the regime obviously depends on the attitude of the parents. It has not been easy to overcome worry and anxiety about what the children eat. Nor has it been easy to avoid showing annoyance at unconventional behavior and food jags. It is also clear that the example of the parents in eating and liking a simple diet and eschewing too highly processed foods is of basic importance.

The program can certainly be carried out more conveniently and happily when the children eat by themselves. Observations at the homes of friends have demonstrated the ease with which parents become short tempered when small children eat at the same table with grownups.

The diet as outlined may involve extra expense for the home, but there is no reason why the same method cannot be attempted with careful planning

on any budget. Raw foods have many advantages but they are not necessary to the success of the regime. It may be thought undesirable to have so much food consumed between meals, but it is believed that the children in this record would not have taken so many fruits and vegetables if they could be eaten only with meals. The older girl, since starting kindergarten and school, obtains less between meals without complaining. One big problem comes in avoiding the excessive consumption of sweets away from home and on special celebrations. This difficulty the parents have to manage to the best of their ability with ingenuity and forethought.

SUMMARY

A modified method of free choice in eating is possible for preschool children in the home without undue effort or expense. The 2 children in this record are healthy and happy. They take an adequate diet and are developing conventional eating habits in their own time.

BCG Vaccination in New York State

The New York State Department of Health and the Medical Society of the State of New York have recently published a *Program and Guide for Physicians on BCG Vaccination*. The brochure discusses the administrative aspect, the recommendations for use in selecting groups to receive the vaccine, the participation in the program by local agencies, the distribution in the state of the vaccine, the recommended procedures, and a technical guide for physicians.

At the present time BCG vaccine manufactured by the State Department

of Health is distributed on request to local full-time health departments, to medical colleges and teaching hospitals, to superintendents of public tuberculosis hospitals, and directors of tuberculosis clinics, and to certain additional institutions who train physicians who have been designated by the State Commissioner of Health to administer BCG vaccine.

Of the methods for vaccination, the multiple puncture method is set forth first, with descriptions of Birkhaug's and Rosenthal's techniques. Also described are the scarification and intracutaneous methods.

Nutrition Appraisals in Mexico*

RICHMOND K. ANDERSON, M.D., F.A.P.H.A., JOSÉ CALVO, M.D., WILLIAM D. ROBINSON, M.D., GLORIA SERRANO, M.D., AND GEORGE C. PAYNE, M.D., F.A.P.H.A.

DURING the years 1942-1945 inclusive, a series of nutrition appraisals were carried out in selected population groups in several areas on the high central plateau of Mexico under the coöperative auspices of the Mexican Ministry of Health and the International Health Division of The Rockefeller Foundation.† Although the results of these investigations have been reported,¹⁻⁴ it seems worth while to summarize them briefly here and to present certain additional data^{5,6} so that a more comprehensive picture of the nutritional status and food habits of the Mexican people may be available.

The work already reported included a study of the nutritional conditions of the residents of the crowded Santa Julia section of Mexico City (altitude approximately 7,500 ft.), occupied by economically poor wage earners¹; a special study of a group of women in this area during pregnancy and after delivery³; an appraisal of the condition of a number of economically poor families before and after they were fed for periods of 8 to 16 months at a government operated dining room (comedor)

in Mexico City²; and a study of the dietary habits and the nutrition of Otomi Indians in four villages in the Mezquital Valley about 75 miles north of Mexico City (altitude approximately 6,500 ft.), unquestionably one of the poorest areas of the country.

In addition, observations have been made in the small village of Yustes in the Bajío area of the State of Guanajuato (altitude approximately 6,000 ft.),⁵ and in the village of Capula, near Lake Patzcuaro, in the State of Michoacan (altitude about 6,200 ft.).⁶ Yustes lies in one of the country's richest agricultural regions, formerly occupied by large haciendas which are now divided and turned over to the villages as communal lands and parcelled out among the families for cultivation. Most of the families have enough land to produce food for their own needs and to furnish cash incomes to provide for other necessities of living. The residents of this village, alone among the groups studied, were probably not restricted as to caloric intake because of poverty. They are chiefly of Otomi Indian ancestry but have some admixture of white blood. The inhabitants of Capula are predominantly Tarascan Indians, although they no longer use their native tongue and many have abandoned their native customs. They engage in agriculture, pottery making, and charcoal production. Economically they are somewhat poorer than the Yustes families but are better off than the other groups studied.

* The studies and observations on which this report is based were conducted under the auspices and with the support of the International Health Division of The Rockefeller Foundation in coöperation with the Ministry of Public Health and Welfare of Mexico, and its subdivisions—the National Institute of Nutrition and the School of Hygiene.

† Studies made under the auspices of the Pan American Sanitary Bureau, the Department of Nutritional Biochemistry of the Massachusetts Institute of Technology (supported by the Kellogg Foundation), the Mexican Ministry of Health and Welfare, and the International Health Division of The Rockefeller Foundation, supplied information for an evaluation of nutrients in Mexican foods.

PROCEDURES

The family was the unit of investigation in every study. Individual diet records, usually for a 7 day period, were compiled for each member of the families participating in a study. A medical history was obtained for each individual, and each was examined for signs or symptoms of deficiency diseases. The slit lamp and biomicroscope were used for examination of the cornea, bulbar conjunctiva, gums and tongue. From each person over 2 years of age approximately 20 ml. of blood was withdrawn for laboratory examination. Four ml. of each sample was oxalated with a mixture of dried potassium and ammonium oxalate⁸ and used for the hematologic examination, including hemoglobin⁹ and hematocrit⁸ determinations and red cell count. The remainder of the sample was used for determining the total serum proteins and albumin by the quantitative biuret method,¹⁰ the serum carotene and vitamin A,¹¹ and the ascorbic acid.¹² For children between 2 and 5 years of age alkaline serum phosphatase was also determined.¹³ In areas where malaria and intestinal parasite infections were prevalent, blood smears were examined for the presence of plasmodia and stool examinations were made. Such examinations were also made in other areas in special cases.

Diet Records—Each family in a study area was visited daily for one week, usually at the time the main meal was being prepared. The composition of the meal was recorded, and the weights and volumes of the foodstuffs used were determined by means of a beam balance and measures. The record of all food consumed by individual members of the family each day was kept on the basis of household measures or in terms of portions of the various dishes eaten by each person. In so far as possible, foods eaten away from home were also recorded.

On the day of the first visit to a family an inventory of the food in the house was taken, and a record was kept of that acquired during the week. Waste was accounted for as far as possible. At the end of the week a second inventory of food was taken. These inventories, together with the record of food purchased or acquired were compared with the amount consumed so that discrepancies might be detected. From the record of food consumed by each individual the average daily intake of calories, animal and total protein, carbohydrates, fat, vitamin A, thiamine, riboflavin, niacin, ascorbic acid, calcium, phosphorus and iron was calculated.

The food tables used in the study of the Santa Julia area were compiled chiefly from the English literature since at the time of that study no analysis of specifically Mexican foods for vitamin and mineral content had been made. Tables used in later studies were based chiefly on analyses of foods collected in Mexico during the time of these studies, many of them from the regions being surveyed.⁷ Although the number of samples was limited, the error was probably less than when calculations were based on data on foreign foods.

No corrections for cooking losses were made. Tortillas, the outstanding constituent in the Mexican diet, were analyzed as prepared for eating. Chili peppers, both dried and green, are commonly ground and eaten without cooking. Most fruits are eaten raw. Where greens are used they are usually not cooked excessively. Beans are frequently boiled for long periods and often fried after boiling. Under these circumstances it seemed inadvisable to assign an arbitrary figure for loss of nutrients in cooking.

FOOD HABITS

The Mexican diet is basically that of

the aboriginal Indian, influenced to a greater or less extent by the Spanish and succeeding immigrations, and by family economic status. Tortillas, which are made of corn, furnish for some families from 75 to 80 per cent of the total calories consumed; in the quantities eaten they are important sources of protein, carbohydrate, fat, thiamine, niacin, calcium, phosphorus and iron. Corn is also used in the form of "atole," a beverage; in "posole," a soup; and in tamales. In the cities, wheat is tending to supplant corn as a basic cereal. Beans of many varieties are eaten, occupying much the same place that potatoes do in many North American diets. Chick peas (*garabonzos*) serve both as an animal and a human food in certain regions.

Meat is eaten by families at higher income levels, but the Mexican diet as a whole is poor in animal proteins. Except on certain large ranches, few cattle or poultry are raised, and the meat produced is usually sold to buy foods of higher caloric value in relation to cost. Milk is consumed by persons in the higher income groups of the larger towns, chiefly through the practice of drinking "café con leche," a mixture of half or more milk with coffee, usually at the evening meal. Among less favored groups in rural areas, milk plays an insignificant role in the diet.

Although the fruits of Mexico are varied, palatable, and nutritious, they are frequently neglected in the diet. In some arid regions the flowers, fruits, and leaves of certain cacti are important sources of nutrients, particularly vitamin C. Pulque, a weakly alcoholic drink (3 to 5 per cent) prepared from the juice of the century plants growing on the high central plateau, provides good amounts of vitamin C and other vitamins when drunk in large quantities. While the beneficial effects of pulque may be questioned, it would be unwise to discourage its consumption in mar-

ginal areas unless more desirable sources of these vitamins can be substituted.⁴

Most of the vegetables common in the United States, as well as others, are available in Mexico, but individual consumption is low among the poorer groups. Truck gardening usually centers about large cities; in rural areas there is little home gardening. Wild plants, many of them nutritious, are consumed by persons of low income.⁴ Chile peppers, which are rich in vitamins, are widely eaten.

The chief meal of the day is usually eaten in the early or middle afternoon. Among the higher income families it includes several courses and a variety of meats, fruits, and vegetables. Among poorer families it usually consists of a beverage or soup, tortillas, beans, and perhaps a little meat or some vegetable, heavily seasoned with chili peppers. On weekly market days, on the many fiesta days, and on Sundays, larger amounts of meats, fruits, and vegetables, plus alcoholic beverages, may be consumed at this meal.

INTAKE OF NUTRIENTS

Table 1 contains the calculated average daily intake of calories, proteins, vitamins, and minerals per person in the various groups studied. These averages are compared in each instance with the National Research Council's recommended allowance for moderate activity, corrected for the age and sex distribution of the persons included in each survey. The recommended averages as corrected for these factors are low for the "comedor" families because of the large percentage of children in this group.²

Except in one group, the caloric intakes were below the recommended allowances, but they were not so low as those reported for several groups studied in the United States.¹⁴⁻¹⁶ They varied directly with the economic status

TABLE 1
Average Daily Intake of Nutrients

| Group | Santa Julia, Mexico City,* Altitude 7,500 ft. | "Comedor," Mexico City | Otomi Indians, Mezquital Valley | Yustes, "Bajio" Area, Guanajuato | Capula, Lake Patzcuaro, Michoacan |
|----------------------------|--|---------------------------|---------------------------------------|--|---|
| Number of diets | 540 | 413 | 856 | 151 | 137 |

| Ca/P ratio | 1.5 | 0.64 | 0.75 | 0.61 | 0.60 |

* The dietary calculations in this study, which were based chiefly on U. S. food tables, are not strictly comparable with the others for which values of Mexican foods were used. These Mexican values resulted in some rise in the calculated amounts of vitamins C and A, and some decrease in those for riboflavin, calcium, and phosphorus, with levels for the other nutrients remaining approximately the same.²

of the groups: the intake (2,528 calories) for the Yustes families, whose consumption was not limited by economic factors, slightly exceeded the recommended allowances for moderate activity. Although it may not be true that intakes as high as this promote optimum health, it was our impression that the individuals in this group had the best physiques.

In all groups the calories were derived chiefly from carbohydrates (65 to 75 per cent), with fat furnishing from 10 to 25 per cent and protein from 10 to 15 per cent. The average total pro-

tein intakes in all sections were good, with the lowest being 80 per cent of that recommended. The amount of animal protein consumed was small, however, and many persons ate no protein of this type during the week the diet record was kept. The main sources of protein were corn¹⁷ and beans.

Vitamin A intakes varied from 45 to 127 per cent of the recommended amounts, and vitamin C intakes from 22 to 141 per cent of these amounts. Excellent intakes of both vitamins are recorded for the Otomi Indians of the

Mezquital Valley, whose extreme poverty forced them to eat plants not ordinarily consumed, many of which were found to have a high content of these vitamins.^{4, 7} Furthermore, these Indians drink pulque in large amounts, thus adding to their vitamin C intake. In the other groups, chili peppers were probably the best single source of vitamins A and C.

Thiamine intakes were more than adequate for each of the population groups. Tortillas were by far the chief source, but inasmuch as the amount of this vitamin attributed to tortillas is based on the analysis of only a few samples, the values given may be somewhat inaccurate. Beans constituted the second most important source of thiamine.

Except in the Santa Julia group in Mexico City, the average intakes of riboflavin were less than 50 per cent of those recommended. Improvement in riboflavin intake is one of the most urgent nutritional needs in Mexico today. Milk, high in riboflavin content, is available only in small quantities, and an early increase in its production cannot be anticipated. Attempts to discover and to raise plants that will constitute new sources of this vitamin would therefore seem worth while. Tortillas, though not high in riboflavin, furnish the major proportion of this vitamin in the diets because of the large quantities consumed. Beans rank next in importance.

Niacin intakes varied from 50 to 80 per cent of those recommended and were derived largely from corn, i.e., tortillas. Some was obtained from beans and meat. Considering the level of the niacin intake and the high corn consumption, it is surprising, in view of the counteracting effect of corn on this vitamin, that more cases of severe niacin deficiency, including pellagra, were not encountered.¹⁸ There are no data on the relation of tryptophane in

the Mexican diet to the niacin requirement.¹⁹ Because the consumption of meat and other animal protein is so low in many areas, these cannot be the major sources of tryptophane. Many beans, particularly of the black variety,²⁰ have a rather high content of this amino acid, but bean consumption was not great in some of the groups studied. Pulque may also contain this amino acid, but many persons take little or none of this beverage. Controlled studies on the factors in the Mexican diet which influence the niacin requirement are needed.

In all groups the average iron intakes were well above those recommended. Calcium and phosphorus intakes were fairly good and the calcium-phosphorus ratios were reasonably favorable. The chief source of both of these minerals was the tortilla. In view of the extremely small amount of milk available in Mexico, it is fortunate that the manner in which tortillas are prepared adds large quantities of calcium to the diet.²¹

No attempt was made in these studies to measure the vitamin D intakes. The average Mexican can, through exposure to intense solar radiation, acquire more than a sufficient amount of vitamin D. The use of fish liver oils or other vitamin concentrates was negligible.

RESULTS OF PHYSICAL EXAMINATIONS

The most conspicuous clinical signs of nutritional deficiency that we observed, not only in the areas where our intensive studies were made but in practically all the regions we visited, were cheilosis (angular stomatitis) and glossitis, which are usually attributed to absence of components of vitamin B-complex from the diet. The small amount of therapeutic testing that we did suggested that riboflavin deficiency was chiefly responsible for the angular stomatitis. Most cases of glossitis appeared to be of a chronic type and due to a mixed vitamin

B deficiency. The Mexican habit of eating large quantities of hot chili peppers may have contributed to the glossitis. Among the few persons to whom we gave test treatments for this condition some responded to riboflavin and some to niacin alone, but the most favorable response appeared to follow whole B-complex therapy. Skin changes such as dryness, scaling, induration, and "crackling" were common, but it was difficult to determine to what extent these might be due to poor personal or environmental hygiene and exposure to adverse climatic conditions.

We saw no pellagra in the groups studied, and Yucatan was the only region we visited in which it was an important endemic disease. Although we made no nutrition studies on hospitalized patients, we visited hospitals in Mexico rather frequently. Among patients in these institutions cases of severe nutritional deficiency, particularly those due to B-complex lack, including pellagra, appeared to be more common than in the United States.

The incidence of corneal vascularization was not high in the areas studied as compared with that observed in the United States,^{1-4, 14, 29, 30} despite the low riboflavin content of the diets. We have had difficulty in correlating corneal vascularization either with riboflavin intake or with other signs suggestive of deficiency of this vitamin, and we question the specificity of this sign, particularly when it is mild in degree and not accompanied by other evidence of riboflavin lack.

No peripheral neuritis or other clinical entities definitely ascribable to thiamine lack were observed in the surveys, which was not surprising in view of the adequate intakes of this vitamin in the populations studied. Persons with vague subjective symptoms and mild degrees of calf tenderness were encountered, but these symptoms in themselves do not necessarily indicate thiamine deficiency.

We saw no definite clinical symptoms of vitamin A deficiency among the populations surveyed. Xerophthalmia is observed occasionally in infants in Mexican hospitals, but we encountered none in our studies. We saw no conjunctival spots which appeared to be true Bitot spots. Mild skin folliculosis was common and persons with well marked follicular hyperkeratosis were occasionally seen. We doubt, however, whether such signs are diagnostic of vitamin A deficiency in the absence of other evidence.

Slit lamp examination of the bulbar conjunctiva revealed a high incidence of changes sometimes attributed to vitamin A deficiency.²⁷ These changes appeared at an earlier age and were of a more severe grade than conjunctival changes seen in the groups studied in the United States. However, no direct correlation was demonstrated between blood serum levels or dietary intakes of vitamin A and these lesions,²⁸ either among individuals in the same group or between average values from group to group. In fact the Otomi Indians, with the highest intake of vitamin A and the best average blood level of this vitamin, exhibited the highest degrees of conjunctival changes.⁴ These people also suffered most from exposure to intense sunlight, wind, and dust, which may have contributed to the membrane changes.

Gingivitis was prevalent in all areas studied, but no correlation could be demonstrated between vitamin C intakes or blood serum levels and this condition, either among individuals or groups. The Otomi Indians, with the worst gums we have ever seen, had the highest blood levels and the highest intakes of vitamin C of any group studied.⁴ The role of other vitamin deficiencies in this disease, particularly deficiencies of the B-complex, needs further investigation, but we believe that the gingivitis which we encountered in

Mexico was primarily due to poor oral hygiene.

No cases of clinical rickets were observed in the surveys, which was to be expected, in view of the intense solar radiation to which most Mexicans are exposed. However, occasional cases of rickets are seen in Mexico, particularly in hospitals. Mothers sometimes shield their young children entirely from the sun, believing that its rays are harmful to them.

The teeth of the average Mexican were found to be excellent. In some rural areas nearly 50 per cent of the adults had perfect teeth.^{4, 5} Fluorosis is certainly a factor contributing to this condition in many regions, and severely mottled enamel is not uncommon. In other regions, however, the fluorine content of the water probably did not account for the excellent condition of the teeth.⁴ It is believed by many that the amount of calcium consumed in tortillas may explain the phenomenon. Further studies, however, are desirable.

Underweight persons, as defined by the usual standards, were common in the groups studied, and the absence of obesity was conspicuous. It is well known that undernutrition, unless grossly unbalanced, may result in a retarded growth, thinning of body tissues, and lack of physical well-being rather than in specific signs of deficiency. Such effects of a poor nutrition would be most evident during the growing period. It should not be inferred, however, that the United States type of growth and physique would suit the Mexican better than his own. The average Mexican is probably less active than the average American, but he can, when necessary, carry heavy loads great distances and do work that few Americans would think of attempting.

Of particular interest among the physical findings not obviously related to nutrition was the rarity of hypertension in the groups studied

and its lack of severity when present.

RESULTS OF BLOOD EXAMINATIONS

The average hemoglobin and average blood serum levels of vitamin A and vitamin C for each of the population groups studied are shown in Table 2 according to age groups. The hemoglobin averages are considerably above those found in surveys in the United States, undoubtedly chiefly because of the altitude of the Mexican communities, although the high iron intakes of the people also probably contribute to the satisfactory levels. Red cell counts and hematocrit values were omitted from the table because they were found to be in conformity with the hemoglobin averages. There was, however, a slightly high mean corpuscular volume which might be ascribed to the altitude or possibly to nutritional causes.^{3, 22}

Of the two Mexico City groups studied, the persons participating in the "comedor" experiment showed significantly lower average hemoglobin levels, which may have been due partly to their poorer diets before they attended the government-operated dining room. Average hemoglobin levels for the other three population groups, all at similar altitudes, were virtually identical in spite of the fact that the areas were widely separated and inhabited by people of different racial characteristics and economic status.

Blood serum levels of vitamin C among children were good. The levels in general were somewhat higher than might have been expected from the intakes of this vitamin. This may be attributable in part to the small average size of the Mexican and to the fact that the records of intakes of vitamin C were incomplete because of the difficulty of obtaining accurate information as to the fruit and the drinks containing fruit juices which were consumed away from home between meals. Low levels of vitamin C were observed in pregnant

TABLE 2
Results of Blood Examinations

women.³ The Otomi Indians had the highest ascorbic acid serum levels of all the groups studied.

Serum vitamin A values for most of the individuals in the areas surveyed, as well as for others for whom these values were determined in the same laboratory, approximated those commonly found in the United States. However, in the Yustes and Capula areas the average values, particularly among children, were lower than those usually encountered. The groups with the higher vitamin A intakes had the higher average serum levels. Few of the levels were in the range of those ordinarily associated with clinical vitamin A deficiency,²³ and no persons with classical symptoms of vitamin A deficiency were observed.

Since, from a clinical standpoint, vitamin B-complex deficiency was the main one encountered, it is unfortunate that no practical tests for its presence applicable to population groups have been developed. Under the best controlled conditions the value of excretion tests on urine may be questioned, and under survey conditions even single samples are sometimes difficult to obtain. However, in the hope that information of

significance regarding a group as a whole might be obtained,²⁴ in the Yustes and Capula surveys riboflavin was determined in single samples of urine,²⁵ and in the Capula survey F₂ (methyl-nicotinamide) was also measured.²⁶

Results of the riboflavin excretion tests in Yustes are summarized in Table 3. In view of the low riboflavin intakes, recorded for this area (Table 1) and the prevalence of clinical signs of the lack of the vitamin, the low excretion levels were not unexpected. Sixty per cent of the values were below 0.3 mg. per liter, the minimum normal level suggested by Feder, *et al.*²⁴ Although there was a wide overlapping in values, the average excretions for persons with cheilosis were less than half those for the group as a whole. In spite of the errors involved in the use of single samples, the observation suggests that riboflavin deficiency is related to this clinical sign.

Of the group at Capula, for which F₂ determinations were performed, 8 per cent excreted no methyl-nicotinamide, and among pregnant and lactating women 17 per cent excreted none. Glossitis, which was probably partially due

* Expressed in terms of milligrams per liter

to niacin deficiency, was common in this group, but the meaning of low or absent F_2 excretions in the urine is too obscure at present to warrant drawing conclusions.

Alkaline serum phosphatase determinations performed on children between 2 and 5 years of age rarely showed values above normal, and they showed none within ranges usually associated with severe clinical rickets.

Serum protein levels were adequate. In Mexico, as in the United States, we have been impressed with the fact that few low blood protein values attributable to poor nutrition were encountered in general population groups. Cases of edema were rare and when found could usually be ascribed to concurrent disease rather than to low blood proteins.

SUMMARY AND CONCLUSIONS

Studies of the nutritional status of several population groups on the high plateau of central Mexico have demonstrated that the common dietary pattern is fundamentally sound. This pattern is based on a liberal consumption of tortillas, beans, and chili peppers, supplemented to a greater or less extent with foods obtained locally. However, the caloric intake is low, little animal protein is consumed and insufficient amounts of riboflavin and niacin are

obtained from the diet. Thiamine and mineral intakes are in general good.

Clinical evidences of nutritional deficiencies were uncommon in the population groups studied, but there were indications of mild deficiencies, particularly of lack of vitamin B-complex. By United States standards the growth of Mexicans is retarded and their stature is small; but racial and other factors, besides nutrition, may contribute toward these physical characteristics.

Hemoglobin levels were excellent, partly because of the altitude and partly owing to the large consumption of iron. Anemia was not often noted.

Definite clinical evidence of deficiencies in vitamins A and C were rare. Blood serum levels and dietary intakes of vitamin A varied from good in some groups to moderately low in others. The average blood serum level of vitamin C for one population group was unusually good owing chiefly to the consumption of pulque, a mildly alcoholic drink which in the quantities taken was a good source of this vitamin. Blood serum levels of vitamin C in the other population groups were less favorable and intakes were low by present standards.

While there is need for improvement in the quantity and quality of the average Mexican diet, attempts at modification should take into account the fact

that there is much of nutritive value in the food usually consumed. To try to impose the food pattern recommended for a United States population upon a country like Mexico, with its present food resources and economic and social conditions might lower rather than improve the nutritional status of the people.

NOTE: We wish to express our appreciation of the coöperation and facilities afforded us by Dr. Francisco de P. Miranda, Director of the Institute of Nutrition, Dr. Manuel B. Marquez Escobedo, Director of the Training Center of the School of Hygiene, and Dr. Angel de la Garza Brito, Director of the School of Hygiene, without whose assistance and support these studies would not have been possible. We are also indebted to our technical staff for their capable assistance, particularly to Sr. Leobardo B. Terpan, Srta. Mercedes Prieto Lopez, Srta. Consulo Sanchez Mesa, and Srta. Antonia Montano S.

Development of a Voluntary Agency for Venereal Disease Control*

HERBERT H. COWPER, M.D., M.P.H.

Los Angeles City Health Department, Division of Venereal Disease Control, and the Venereal Disease Council of the City and County of Los Angeles, Inc.

IN 1841, a Frenchman who had visited America wrote the following:

Americans of all ages, all conditions and all dispositions constantly form associations . . . religious, moral, serious, futile, extensive or restricted, enormous or diminutive . . . If it be proposed to advance some truth, or to foster some feeling by the encouragement of a great example, they form a society. Wherever, at the head of some new undertaking, you see the government in France, or a man of rank in England, in the United States you will be sure to find an association . . . I have often admired the extreme skill with which the inhabitants of the United States succeeded in proposing a common object to the exertions of a great many men, and in getting them voluntarily to pursue it.^{1, 2}

The "common object" for the Los Angeles Venereal Disease Council was arrived at during a teaching program in which nurses in service, students from the University of California, and three schools of nursing were oriented in public health as practised by the Los Angeles City Health Department in a program consisting of two days of formal lectures on venereal diseases and one month of practical experience in the department. Organized to meet the requirements of the State Board of Nurse Examiners, the first course was held toward the end of August, 1943.

This teaching program, as well as the Venereal Disease Council, was conceived and developed by a state public health nurse assigned to the Los Angeles City

Health Department. She had had experience with a lay organization for the advancement of public health in Alameda County. She had seen the usefulness of that organization in promoting public health, supplying the official health agency with needed personnel and equipment items, and in bringing to the attention of civic governing bodies the importance of an adequate budget for health. Certain guiding principles in organization were obtained from publications of the American Social Hygiene Association.^{3, 4}

The third lecture series for nurses was expanded to include a few guests from health and welfare agencies. Other social agencies became attentive and the fourth series of lectures was attended by approximately 100 persons, some attracted by newspaper publicity given to the meeting. At this institute of November 19, 1943, on the medical, public health, social, and psychiatric aspects of venereal disease control, a panel discussion aroused such interest and so many unanswered problems that members of the panel met formally at a later date to discuss plans for organized venereal disease education in city schools.

As a result of general interest, ideas unfolded. Some thirty-two additional persons, representing City and State Departments of Health, schools and colleges, newspapers, police officers, radio studios, medical specialists, labor, Parent-Teacher Association, League

* Address presented at Western Venereal Disease Control Officers' Conference, San Francisco, Calif., May 25, 1947.

of Women Voters, Council of Social Agencies, American Institute of Family Relations, and Catholic, Protestant, and Jewish church representatives accepted invitations to join the original panel group of seven. The City Health Officer called the first committee meeting December 7, 1943. Some twenty-five attended. A temporary chairman and a secretary were elected. The chairman appointed finance, planning, and nomination committees. A short talk on present venereal disease control activities was delivered. Committee members suggested that more work should be done in public education, school education, and in the rehabilitation of sex delinquents. A resolution was adopted requesting that the Surgeon General make permanent recordings of the K.F.I. radio broadcasts on venereal diseases, which at that time were receiving national attention.

The planning committee met again in December to prepare for a general meeting on January 20, 1944. Fourteen more members were added, including representatives from the Merchants and Manufacturers Association, Hollywood, political organizations, courts, various governmental institutions, and other health department members. At the January meeting it was reported that, due to the influence of the Council, the Parent-Teacher Association had employed a nationally known authority on sex education for the purpose of instructing teachers in facts and methods of presenting sex education in primary and secondary schools. This program was approved by the Board of Education. Teacher credits were allowed. At the same meeting, a well known family relations expert delivered a talk on divorce in relation to venereal disease, and a professor of psychology of a local college presented plans for a psychologic work-up for venereal disease inpatients. It was thought that individual findings of the latter study

could be useful in making referrals to the rehabilitation program of the California Youth Authority. During this second meeting, the desirability of having an executive secretary who would carry out the instructions of the committee, was mentioned.

The group formally went into action February 10, 1944. Regular officers were elected, an executive committee was selected, the name "Coördinating Committee for Venereal Disease Control" was chosen, subcommittees on finance, publicity, education, institutes, and psychologic studies were appointed, and a statement of purpose was formally adopted.

The statement of purpose reads as follows:

It is the purpose of the Coördinating Committee to serve as a clearing house, information center, and medium of exchange for various community organizations which have to do with problems relating to venereal disease control in its broader aspects; to stimulate interest in problems that need attention, and to extend and facilitate the services of the health department in the control of venereal disease. The Coördinating Committee is not an operating organization but functions in an advisory, promotional and coördinating capacity. Through its services the work of other community agencies in the solution of venereal disease and related problems is to be promoted as well as that of the health department.

This purpose of the organization is in effect that of any non-professional and nonofficial voluntary health agency. It is promotional in character, utilizing the methods of education, publicity, and propaganda to achieve the two essential needs: (1) justification—by carrying the gospel, and (2) perpetuation—by attracting new members and new support. It also enlarges the field of activity to include the basic factors of promiscuity and "average of concern for body health" in the spread of venereal disease as related to education, opportunity, housing, medical care, and other normal human growth requirements. In line with current thought,

the committee was not to carry out operational functions. However, some operational tasks are necessary even to a voluntary health agency. Some tangible demonstration of usefulness and some promotional springboard, such as chest x-rays or blood tests, must be carried out.

Following the formal organization of the committee, rules of membership, policy statements, and a constitution were formulated by the executive committee and adopted by the membership. At each subsequent regular monthly meeting, leaders in governmental and voluntary agencies presented formal talks on their activities in relation to venereal disease control. Speakers included members of the police department, judiciary, Department of Institutions, Mayor's office, and Social Protective Division of the Federal Security Agency. Since the Venereal Disease Council was nonofficial and responsible only to itself and the public, it could, and did, scrutinize the activity of every agency. Mystics and logicians alike were granted impartial hearings.

In 1945, the committee was well under way. Early in the year a resolution memorializing the Mayor and City Council to study ways and means for increasing the health budget, was drawn. This resolution was in turn backed by the Association of School Physicians, Council of School Nurses, the Junior League of Los Angeles, Los Angeles Central Labor Council, Southern California Association of Life Science Teachers, Tenth District Parent-Teacher Association, California Protective Society, Health Division of Welfare Council, League of Women Voters, Los Angeles County Probation Committee, and a Teachers' Union. In later meetings with the Mayor, supported by Army, Navy, and Public Health Service officials, an emergency increase of approximately \$78,000 per year was obtained for the health de-

partment. This, in my opinion, has been the greatest contribution of the committee.

At about the same time, connection with the Columbia Foundation³ was established, and arrangements were made for the committee to receive a grant of \$10,000. This fund was made available for one year, during which time the committee was to demonstrate its worth to the community. Support during succeeding years was, in the Foundation's judgment, to come from other sources. The committee incorporated under the title of the "Venereal Disease Council of the City and County of Los Angeles," a name adopted earlier to eliminate the objectionable and indefinite terms of "Coördinating" and "Control" and to widen the area to be served.

An excellent selection was made in employing an executive secretary who was well qualified, scholastically and by experience, and was very personable. This selection was possible during a time of acute labor shortage because of a relatively high salary. He began work in July, 1945, 1½ years after formal organization of the committee. There can be no doubt about the wisdom of this move, yet in retrospect it seems that the Council members' participation decreased slightly while the executive secretary's responsibilities increased.

A diagrammatic picture of the organization from its inception to January, 1947, is presented by the following list of projects and accomplishments. The Council:

1. Revealed as a result of a telephone survey that social agencies lacked information but had an enthusiastic desire to participate in the program.
2. Instituted psychologic work-ups consisting of psychometric tests, personality inventories and aptitudes, on venereal disease patients.
3. Secured Parent-Teacher Association funds and sponsorship for a series of lectures

over an 18 month period on sex education. Approximately 850 persons completed the course.

4. Surveyed prison facilities for prostitutes and encouraged improvements in jail recreational and rehabilitation programs.

5. Compiled a bibliography on the venereal diseases for public libraries.

6. Actively supported the health department in a substantial improvement in the budget for personnel.

7. Supported increase in salary for public health nurses.

8. Developed with the Board of Education a sex education lecture series for mothers attending child health clinics.

9. Submitted a resolution to the Board of Education requesting an exploration of needs and methods of sex education in public schools. This was formally acknowledged by the Board which authorized the formation of a study committee of experts and interested persons.

10. Actively assisted in the educational program at the local Rapid Treatment Center, arranging for circulating library service at this institution.

11. Obtained permission of Catholic authorities to resume showings in schools of the film "Know for Sure," which had been withdrawn due to their objections.

12. Supplied and distributed many pamphlets on sex education. Prepared the pamphlet *Do You Know* and posters on the Rapid Treatment Center for clinic patients.

13. Maintained an active program of film showings and lectures on venereal disease for public groups.

14. Materially aided in arranging educational and blood survey programs in six high schools.

15. Planned four large public institutes on all phases of venereal disease control.

16. Interested a local high school to plan and carry out a forum on health and family life for Public School Week. Sixteen schools participated.

17. Prepared material and participated in a weekly radio program on health and family life.

18. Completed a survey of adults regarding their source of sex information and their retrospective views on their schools' program.

19. Explored the need for an adequate teaching film on venereal disease for public schools.

20. Initiated five "work shops" for teachers on Family Life Education. Approximately 150 teachers completed these sessions.

21. Originated a program, with the coöperation of the Southern California Retail Drug-

gists Association, for informing druggists regarding the procedure and importance of the proper referral of venereal disease patients.

22. Suggested the program of monthly mailings to private physicians on venereal disease trends, diagnosis, and treatment.

The sharing of problems and the pooling of experience in their solution, as exemplified in the Council, leads to group participation and group action. The process is slow but effective, and in looking backward, the number of accomplishments is surprising.

During the first part of 1946, the Council was faced with a termination of its funds by July. Several possible alternatives were presented: another grant from Columbia Foundation, which seemed unlikely; a special community solicitation of funds; Community Chest participation or a return to former non-budgetary status. The Welfare Council of Los Angeles, made up of representatives of the Community Chest, recommended that the Council seek affiliation with the Los Angeles Tuberculosis and Health Association, and that if such was accomplished, a grant of \$15,000 would be available for the Council's activities. This was in accord with the general recommendations of the Gunn-Platt report⁶ which suggested the consolidation of voluntary health agencies for the purpose of pooling resources, limiting the number of public appeals for funds, better distribution of expenditures, and for promotion of general health, not specific diseases.

Though there was some disagreement with this report by a member⁷ of its Advisory Committee, it was almost universally agreed that a venereal disease organization could not raise public funds independently, and should properly align with a larger health agency. The Los Angeles Tuberculosis and Health Association was reluctant to include the venereal diseases in its program, but after mature consideration and consultation with the Welfare Council and the California Social Hygiene Association, a

one year trial marriage was consummated on February 19, 1947. The offices of the Council's Executive Secretary were moved to the Tuberculosis Association and the Council suspended its activities in favor of a committee selected by the Executive Board of the Association. Just prior to this union, the Venereal Disease Council affiliated with the American Social Hygiene Association, and will, with the Tuberculosis Association's committee, serve as the local outlet of the American Social Hygiene Association.

It is believed that this change is a step forward for three reasons: (1) A certain organizational stability is gained; (2) the community standing of the Tuberculosis and Health Association lends prestige to venereal disease problems; and (3) the educational and promotional experience and equipment of that agency may be directed to study and combat the venereal diseases. However, certain undesirable elements are attached to this amalgamation, i.e., the enthusiasm that accompanies a new and unconventional organization is lost; the Council is yoked with the traditions, patterns, and dignity of an old and crystallized agency; and, due to administrative policy, those actively concerned with venereal disease control are removed from direct relationship with the new committee.

A story of pathfinding experience has been given. Welfare agencies of neighboring communities in Los Angeles County are seeking similar organizations. According to the American cus-

tom, many such organizations are to be expected. This writer would advise venereal disease control officers to support them in their growth and development. They may be harassing and irritating at times, but they can also be very useful in the general promotion of the control program. Some will no doubt feel that a voluntary agency for the venereal diseases is not justified since the efforts of official agencies are well organized and developed. No one, however, will disagree that promotional activity could be multiplied and improved, or that the underlying factors in the spread of these diseases have scarcely been touched.

Study of Vision Testing Procedures^{*}

THOMAS E. SHAFFER, M.D.

Associate Professor of Pediatrics and Physician, University School, The Ohio State University, Columbus, Ohio

THIS report deals with some observations made during a study of the vision of children carried on at the University School, Ohio State University, in the spring of 1947. The study consisted of a thorough appraisal of the ocular functions of 203 children in the first through the eleventh grades and was a coöperative undertaking by members of the staffs of the College of Medicine, the College of Education, and the School of Optometry. A number of people contributed services and advice, and I am particularly indebted to Dr. Claude S. Perry of the Department of Ophthalmology and to Dr. Glenn A. Fry and Dr. Howard F. Haines of the School of Optometry for assistance in all stages of the investigation.

The main purpose of our study was to evaluate several widely known screening methods for testing visual function and to bring forth, if possible, some facts upon which plans for a vision testing program could be based.

The need for periodic vision testing in schools has been amply demonstrated. School physicians, nurses, and administrators are now faced with the problem of deciding upon the scope and methods to be used in such a program.

Methods and Procedure—By random selection, determined only by the order in which parental permission was re-

ceived, 203 pupils from the 1st through the 11th grades took part in the study. The Snellen Test for visual acuity at 20 ft., the Massachusetts Vision Test,^{1,2} and the Keystone Telebinocular Tests³ were administered to each subject in an unhurried fashion and in quiet surroundings. For the Snellen Test, the illiterate "E" chart, artificially and evenly illuminated, was used. In administering the Massachusetts and Keystone Tests, the procedures prescribed in directions accompanying the apparatus were followed meticulously, except that the three parts of the Massachusetts Test were given, regardless of failure in one part. Additional procedures were employed, including tests for color-blindness, eye dominance, and near visual acuity. The same examiners also made precise measurement, in prism diopters, of ocular muscle functions.

Soon after these tests, but not on the same day, each subject was given a complete examination, with cycloplegia to relax accommodation, by an ophthalmologist. This examination included a search for pathologic conditions within and surrounding the eyes, and determination of refractive error by both retinoscopic and subjective methods. Some time later, after the effects of cycloplegia had completely disappeared, each child was reexamined to determine the amount of correction required to obtain maximal acuity with accommodation functioning. For evaluative purposes in this study, the cor-

^{*} Presented before the School Health Section of the American Public Health Association at the Seventy-fifth Annual Meeting in Atlantic City, N. J., October 6, 1947.

FIGURE 1

FIGURE 2

NOTE: The small bar-graph on the left side of Figure 1 and Figure 2 shows the distribution of cases with refractive error (vertical lines), cases with muscle imbalance alone (vertical lines) and cases with normal vision (unlined) among the total group of 188 children.

rection required at this post-cycloplegic examination has been recorded as the refractive error.

Subjects who wore glasses were usually tested with and without them. With few exceptions the data used for these individuals are the results obtained with glasses, and opinion on need for referral is based on the difference between our refraction and the correction afforded by the subject's glasses.

Results—After elimination of incomplete records due to absence during part of the examination, data on 188 subjects were analyzed. In age distribution, each year of age between 6 and 15 was represented by from 6 per cent to 12 per cent of the total, while ages 16, 17 and 18 made up, respectively about 6 per cent, 4 per cent, and 0.5 per cent of the sample.

Specialists assisting in the study decided on the basis of errors of refraction that 47 cases, or 25 per cent, required treatment or observation. There is an additional group of 14 cases, 7.4 per cent, consisting of children who had no marked error of refraction but who proved to have sufficient ocular muscle imbalance to justify referral, making a total of 61 cases, or 32.4 per cent of the total group, whose detection by screening examination should be expected.* As there is some difference of opinion among specialists concerning the advisability of searching for muscle imbalance uncomplicated by errors of

refraction, this group of 14 cases has been kept distinct and will be considered separately.

Except for the Snellen Test, the standards for referral or failure were those prescribed in directions received with the equipment. In the Snellen Test, children 7 years of age and younger were failed (referred) when vision in either eye was 20/40 or worse, while children older than 7 years were failed when either eye had vision 20/30 or worse. Figure 1 shows the performance of the three screening procedures in the group of 47 cases with refractive errors. The Telebinocular disclosed 43, or 91.5 per cent of them, the Snellen Test identified 42, or 89.4 per cent, and the Massachusetts Vision Test revealed 32, or 68.1 per cent. The accuracy with which teachers were able to select children in need of referral is also shown. While this is not a reliable procedure when used alone, teachers did select 25 cases, 53.2 per cent.

The performance of each test among the cases with muscle imbalance, uncomplicated by significant error of refraction, is shown in Figure 2. The Telebinocular Test revealed 11 of 14 cases, and the Massachusetts Vision Test disclosed 8 cases. It is interesting to note that 9 of the cases would have been referred for further examination on the basis of the Snellen visual acuity results, although that test is certainly not specific for imbalance.

With regard to ocular muscle balance, comparison of results from the tests specific for lateral imbalance from the Telebinocular and the Massachusetts Tests is worthy of note. The amount of esophoria or exophoria was accurately measured by optical prisms for comparison with screening results. In Figure 3 it is seen that in the test at 20 ft. the Massachusetts Test rarely fails a case unnecessarily, but does miss cases it is constructed to detect. The Telebinocular Test refers a great many

* Need for referral was established on these criteria: *Spheres*: +1.50 diopters or more; any amount of minus. *Cylinders*: under 13 years of age, -0.75 or more; age 13 years and over, -0.50 or more. *Phorias*: more than 6 prisms of esophoria or 4 prisms of exophoria at 20 ft., and more than 6 prisms of esophoria or 8 prisms of exophoria at near point; more than 1.25 prisms of hyperphoria.

Except for minus corrections these limits are thought to be too generous, especially for older children; but more rigid limits than those specified in the tests would have made impartial evaluation impossible. With respect to myopia, it is our belief that any degree of near-sightedness should be detected early and that the child, particularly an adolescent, should be under observation even though glasses may not be indicated at the first referral.

FIGURE 3

cases needlessly, but rarely misses significant ones. A similar pattern was found for each test in the case of imbalance at the reading distance.

Results from each test in the group of 127 cases considered as having no significant visual problem are as follows: Sixty-eight, 53.5 per cent, of these failed the Telebinocular Test; 28, 22 per cent, failed the Snellen Test; and only 2 cases, or 1.6 per cent, did not pass the Massachusetts Test.

We do not feel prepared at this time to make a final statement on the plus-sphere test. The test is based on sound physiological principles. Its usefulness, however, is limited by the small number of children who have sufficient degree of simple far-sightedness to accept a

correction of $+1.50$ sphere. The test, in our study, was found to refer many children unnecessarily. In 6 instances 20/20 vision through the plus-sphere was recorded, when, according to refraction findings, this should not have occurred. There were many more occasions when 20/30 vision was noted without apparent justification. Technical errors may have been responsible, but it is doubtful whether the test will ordinarily be given under such favorable circumstances. We have become interested in investigating modifications in the technique of the test because this test theoretically at least should be a valuable addition to a screening procedure. For example, further study is needed to determine the amount of

FIGURE 4

plus-sphere appropriate for testing in different age groups. Hyperopia of less than $+1.50$ diopters may properly be considered normal in very young children. Among older children, however, lesser degrees of hyperopia are significant, and for them it is probable

that a spherical lens of $+0.75$ or $+1.00$ diopters should be used in the test. Another matter under investigation is the length of time an individual should wear the plus-sphere before his visual acuity is determined in this test.

Inclusion of tests for visual acuity at

FIGURE 5

reading distance in school testing programs has been advocated by some. Theoretically such a test is not warrantable, since far-sighted children usually can accommodate sufficiently to pass it, and astigmatic and near-sighted individuals who would fail it would be expected also to fail the distance-acuity test. Our findings support this view, since only one-third of the group needing referral failed the test. Only one subject passed the distance-acuity test and failed the near-acuity test.

Figure 4 depicts the degree of accuracy with which teachers or counselors were able to select the children with significant visual problems. The irregular pattern indicated that the individual ability of each teacher plays a large part in the matter. The good records of several teachers emphasize the contribution which well trained, health conscious teachers can make to such a program.

The time required for administering the Massachusetts Vision Test and the Telebinocular Test was studied in four elementary grades. Students in each grade were divided into two similar groups, and one group in each grade received some preliminary explanation of the tests. The average time needed for students in each group is shown in Figure 5. In addition to the benefits from health teaching, there is a small saving of time in the instructed group which would become appreciable when a large number of children are to be tested.

COMMENT

At this stage in the analysis of our data several comments concerning these vision testing procedures seem justifiable: The Snellen Test for visual acuity at 20 ft. is the most reliable single screening procedure, when car-

ried out carefully and with proper illumination. It should by all means be included in testing programs in schools.

The Keystone Telebinocular, when the entire battery of tests is used for a screening procedure, has a much higher over-referral rate than the Snellen Test and is not significantly more accurate in finding cases in need of referral. Unnecessary referrals, without increased case finding efficiency, are not economical. This criticism does not refer to the possible usefulness of the Telebinocular in investigating readiness for reading and reading failures, a matter we have not yet studied.

The record of the Massachusetts Vision Test, both in selecting cases in need of referral and in the margin of over-referral, seems too low for the purposes of a screening test in schools. Since the Snellen Test is included in the Massachusetts Test, more exacting criteria for referral would achieve at least the efficiency of the Snellen Test as employed in this investigation plus the cases discovered by the plus-sphere and Maddox rods. More rigid standards are particularly needed in the older school-age groups, where even small refractive errors merit careful evaluation. Recommendations with respect to this as well as some modification of the plus-lens test will be included in our final report.

Further analysis of our data is being directed toward recommendations for a simple, effective vision test for use in all school-age groups.

HEALTH AND ECONOMICS

WE are generally accustomed to trace recognition of the importance of economic factors in health to John Howard and Lord Ashley, and Edwin Chadwick and John Simon, the great English pioneers of sanitary reform in the 18th and 19th centuries. The English approach to these problems was, however, characteristically empirical; and its philosophical formulation was handicapped by the dominant *laissez faire* individualism of the times. George Rosen has performed a real service¹ in preparing a scholarly and well balanced "Genetic Analysis" of the concept of "Social Medicine," which we recommend to readers interested in the basic aspects of the problem. The first outstanding thinker in this field (after Johann Peter Frank) was Virchow who said a century ago: "Medicine is a social science and politics nothing but medicine on a grand scale." Edward Reich² in 1871 arranged his *System of Hygiene* under four main headings: Moral Hygiene (including mental hygiene); Social Hygiene (including the problems of poverty); Dietetic Hygiene (including not only nutrition but the whole field of personal hygiene); and Police Hygiene (conventional public health administration). He says, "Because social life depends, on the one hand, on the physical and moral constitution of individuals, and on the other, on property; the measures taken by social hygiene can be effective only if they aim to improve the constitution, and at the same time make possible a natural development of the property relationship. Above all else social hygiene must wipe out poverty, for as long as this exists there can be no question either of improving the constitution or of a normal development of economic relations." Finally, Alfred Grotjahn in the present century conceived clearly the idea of systematic investigation of medical problems in the light of social science, so as "to arrive finally at a theory of social pathology and social hygiene which, with its own methods . . . would be used to investigate and to determine how life and health, particularly of the poorer classes, are dependent on social conditions and the environment."³

An even more exhaustive review of this subject has recently appeared from the pen of René Sand, a distinguished Belgian pioneer in the field of social medicine.⁴ He defines "Social Medicine" as "the art of prevention and of cure, considered . . .

from the point of view of the reciprocal relations which relate the health of men to the conditions of their life." Sand's book is primarily historical and is written with a width of vision not before achieved in this field. He ranges from Egyptian records of 3000 B.C. to the Constitution of the World Health Organization. Major chapters deal with the history of the medical profession in its various social and economic relations; with hospitals, outpatient services, and social service; with personal hygiene, public hygiene, social hygiene, and occupational hygiene; with public assistance; and with the basic sciences relating to man (demography, anthropometry, psychology, sociology, and the like). In a final chapter, Dr. Sand reviews 20th century advances of social medicine in Germany and Austria, France, Belgium, the Netherlands, Italy, Czechoslovakia, Romania, Jugo-Slavia, Great Britain and its Dominions, the United States and Latin America, with an unfailingly keen perception of major trends.

The critical reader may be inclined to point out that the gross social inequalities which stirred Chadwick and Simon, Virchow and Reich in the 19th century no longer exist in the England or the United States of today. This contention is relatively sound. The difference between economic classes has been measurably narrowed so that the condition of what Chadwick described as "the laboring population"—in fortunate countries like ours—has been greatly ameliorated; but the gap has not been closed, as pointed out at our Atlantic City Convention last fall.⁷

The contribution by Terris in this issue of the *Journal* brings out an interesting relationship between economic and occupational status and tuberculosis rates in the City of Buffalo. The mortality from this disease was, of course, higher at low economic levels. For males under 35 years of age and for females at all ages, the figure for the lowest economic group was about twice that for the highest economic group. For males over 35 years of age, however, the figure for the lowest economic group was three and one-half times that for the highest economic group. This excess Dr. Terris reasonably attributes to conditions of occupation.

The same relationship is brought out with striking force in the recent *Statistical Yearbook* of the New York Tuberculosis and Health Association.⁸ The actual death rate for white persons in New York City is almost the same for males and for females up to the age of 34 years (between 18 and 31 per 100,000 at ages 20 to 34). From 35 years on the rate for females drops from 27 at 30-34 years to 16 at 45-49 years and then rises to 34 per 100,000 at 70-74 years. But the rate for white males rises steadily from 31 at 30-34 years to 142 at 70-74 years.

This may be due to some physiological difference between the sexes; but it seems far more probable that the strains of earning a livelihood are the major factors at work.

Social hygiene (in the broad sense) still has its serious problems to be solved.

THE PUBLIC HEALTH NURSE AND THE SOCIAL WORKER

THE present issue of this *Journal* contains at least three articles which involve, in some measure, emphasis on the respective roles of the public health nurse

and the social worker in dealing with important present-day health problems. Perhaps perusal of these articles may stimulate the reader—as it did the Editor—to speculate on the relations of these two professions.

A commonly accepted definition of public health reads as follows:

“Public health is the science and the art of preventing disease, prolonging life, and promoting physical and mental health and efficiency through organized community efforts for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene, the organization of medical and nursing services for the early diagnosis and treatment of disease, and the development of the social machinery which will ensure to every individual in the community a standard of living adequate for the maintenance of health.”

The attempt to find a definition of public welfare which has received a similarly general recognition in that field has proved unsuccessful. The Editor therefore asked two friends, of distinguished eminence in social work, to try their hand at such a formulation—with the following result: “Public welfare (social welfare) is concerned with all activities relating to the well-being of the individual and the group. It encompasses prevention of social disorders, treatment of social maladjustments, and the development of a social order which provides the essentials for a satisfying life. Public welfare is advanced through social and health services to the individual and the group (such as psychiatric and psychological services, social case work, financial assistance, and recreation) social action (such as the organized efforts of the community and legislation), and education.”

The reader will note that public health theoretically annexes the whole field of social welfare under “the development of the social machinery which will ensure a standard of living adequate for the maintenance of health.” On the other hand, social welfare, politely but firmly, takes possession of the field of public health, since “social and health services to the individual and the group” are essential prime elements in the advancement of social welfare.

Both these contentions are entirely sound; and they indicate the need for mutual understanding between two closely related and overlapping professions. The most concrete possibility of jurisdictional misunderstanding lies in the individual home. Most cases of sickness involve social problems; and most cases of poverty are likely to involve health problems. The public health nurse will often need the aid of the family social worker and the social worker will often need the help of the nurse. The primary classification of a given family may be a matter of chance, depending on whether sickness or economic stress happened to cause the primary visit of one or the other field worker. Incidentally, it may be pointed out that the social worker tends more and more to limit her home visiting, believing that the client may be freer to discuss his, or her, problems apart from the family setting, which at a given time may be confused or under tension.

Ideally, as it seems to us, there should be available for any given area a district field worker of each of these two types. In the health field, there is general acceptance of the standard of one public health nurse for every 2,000 people; and this ideal is already realized in our best organized communities. In many rural areas the nurse—for lack of adequate social service—is forced to fill both health and social functions; and in Monmouth County, N. J., such a program is definitely in force. More than fifteen years ago, a public health surveyor had the temerity to suggest that at least one generalized social worker should be provided for every 10,000 persons in the population. If some goal of this sort could be set, it would clarify planning in the wide borderland of health and welfare.

Intelligent coöperation between nurse and social worker should be facilitated

by current trends of thought with respect to the training of the social worker herself. The schools of social work are reconsidering their curricula with a view to developing a more adequate "core program" which would avoid premature specialization but give each student a wider vision of the basic principles in social work (including its health aspects) which are important for the generalized social case worker.

There will be resistance in certain localities to a generalized social case work program, due to the traditional feeling that the worker in a public welfare department who provides direct relief in the form of money grants, food, clothing, shelter, and medical care must deal only with the indigent or the near-indigent. This is, however, a prejudice which is gradually losing its force. A sound public welfare program should include case work service to all families who need such service, whether they also require direct relief or not.

Even, however, if we agree on the desirability of providing for the homes of every area a local field worker in public health nursing and a local field worker in public welfare, we should be only at the threshold of our jurisdictional possibilities. Nearly all health problems and most social problems involve emotional stresses; and the psychiatric social worker comes into the picture. Working out from the hospital and clinic is the medical-social worker. In the health or social agency is the nutritionist. In many localities there may be still other specialists of diverse allied types—dealing with poliomyelitis or rheumatic fever, or deficiencies in sight or hearing.

It is clearly uneconomical and ineffective to have five or six different experts in the fields of health and welfare visiting the home. In public health nursing the ideal of generalized district service has been almost universally accepted—though not as yet always realized. The field worker in such a program *must have enough* training in allied knowledges to know where her own competence ends; and she must have at her disposal expert specialists for consultation in their various fields. There might be real gain in a program under which there were two, and only two, workers for home visiting, the district nurse and the district social worker, both with some training in the elements of mental hygiene—coöperating with each other and relying on the specialist to supplement their less intensive skills. The representative of medical-social service in a hospital or of a local mental hygiene clinic should naturally have access to the home but would go in after mutual agreement with, or referral by, the public health nurse or the family social worker under whose general jurisdiction a given family might be. Perhaps this is a Utopian dream—perhaps just a nightmare. Possibly it may be a problem which the American Public Welfare Association and the American Public Health Association might study to advantage through a joint committee.

CHANGING ATTITUDE OF THE ARMY WITH REGARD TO VENEREAL DISEASES

IT is obvious that the control of the venereal diseases involves two major objectives: (1) reduction of exposure to infection, and (2) prompt treatment of the infected individual.

In World Wars I and II, the Army was not indifferent to the first line of approach. Effective procedures were adopted for controlling areas of prostitution in the vicinity of military encampments, with far-reaching results in the elimination

of red-light districts in many American cities; and, through education and the provision of recreational facilities, every effort was made to reduce promiscuous sexual intercourse. It would only be fair to say, however, that major emphasis in the total program was laid on medical treatment, both prophylactic and curative. The key to this latter approach during World War I was to be found in the provision that a soldier who developed venereal disease without record of prophylactic treatment was penalized, while if he had been recorded as receiving such treatment, he was not. This penalty was eliminated during the Second World War.

Today, the major emphasis of the program has been shifted from medical to moral grounds. A circular issued by the War Department a year ago¹ places responsibility for the whole venereal disease program on command channels and states that "the members of special staffs will be utilized only as technical advisers for that part of the program of venereal disease control specifically allied to their normal functions and responsibilities." The commanders must "impress moral responsibility and encourage strong self-discipline in officers and enlisted men of their command. Special attention will be given to the elimination of officers and non-commissioned officers, who, by the example of their private lives, undermine discipline and respect for command." Elaborate procedures of indoctrination are provided, with emphasis on "self control, self discipline, the worth of right conduct, clean living and its rewards, the obligation of the soldier to the home, the family and the nation." In this indoctrination, "Prophylaxis will be mentioned and discussed in a scientific manner, bringing out its limitations. No more than 10 per cent of the time of one lecture should be expended on the subject of prophylaxis. There should be no mass instruction in the details of prophylaxis. Those who desire this information should be referred to a medical officer for consultation." The chaplain, rather than the physician, is central in this program.

The wartime policies sought to remove the stigma from venereal disease, in order to facilitate prophylaxis and prompt treatment. The present program may seem to the average soldier intended to penalize venereal infection and promiscuity. Commanders must—

"Restrict military personnel infected with venereal disease to the unit areas for a minimum of 30 days, and, on recommendation of the surgeon, up to 90 days after the completion of treatment in order to diminish the chance of relapse or early reinfection and to insure, in the case of gonorrhea, that a co-existing syphilitic infection has not been masked by the treatment for gonorrhea. Individuals infected with venereal disease will not be evacuated to the zone of interior until 30 days have elapsed following completion of treatment. Exceptions to this working quarantine may be made only for medical reasons and when extreme hardship will result."

"In recommending the promotion of individuals and in the preparation of efficiency reports of officers, take cognizance of repeated infections of venereal diseases, intemperance, and similar traits and habits prejudicial to good order and military discipline."

"Restrict passes in the case of irresponsible individuals who repeatedly expose themselves to the risk of venereal disease. The granting of passes is a privilege and not a right and should be a reward of good conduct."

"Give consideration to the separation from the service, under the provisions of existing Army Regulations and directives, of individuals who demonstrate undesirable habits and traits of character including the repeated incurrence of venereal disease."

The working out of this plan at Fort Knox, Ky.² and of a similar plan in the First Army Command Area³ has been described more fully—with editorial comment⁴—in the *Journal of Social Hygiene*. The program as a whole represents a radical reversal of past attitudes—both military and civil—with regard to the control of venereal diseases. Its results will be awaited with great interest. We are informed that Army incidence rates for syphilis and gonorrhea have gone down under

the new policy. It remains to be seen, however, whether such a reduction is real or imaginary. Obviously, the severe restrictions involved and implied, are not likely to stimulate free and ready recourse to prophylactic and treatment services. They might, on the other hand, lead to concealment of infection, recourse to quacks and self-medication, with serious ultimate results. Only time will tell. If the experiment succeeds, it will be a major contribution to our thinking about the whole problem of sex hygiene.

THEY ALSO SERVE WHO ONLY SIT AND WRITE

THE visit of a staff member of the Association to the Spring Meeting of one of its constituent associations (The South Carolina Public Health Association)—in addition to delightful memories of Southern hospitality—brought one quite revealing experience. This was the organized representation of the health department clerical staff on the program. The conference, as usual, had formal group sectional meetings for health officers, nurses, engineers and sanitarians, health educators, and nutritionists; but it had also a sectional meeting for secretaries, stenographers and clerks. We understand that this development is not unique in the South; but it is certainly unusual in most of our state meetings.

We believe that this recognition of a group of workers whose service is so vital in daily routine constitutes a step of primary importance in the development of sound health department practice. The work of the technical expert would be sadly handicapped without the diligence, the accuracy, the imagination—and the diplomacy in public contacts—of the clerical staff. This group of essential public health personnel will function at a much higher level with a broad view of their tasks; any assistance and any encouragement we can give them will be amply rewarded.

Clearing House on Public Health Salary Information

ANNUAL NURSE SALARY STUDY

THE annual nurse salary study of the National Organization for Public Health Nursing was published in three parts in the October, 1947, February and March, 1948, issues of *Public Health Nursing* and dealt with salaries of nurses, clerks, and non-nurse professional workers. The study is based on 641 agencies—state, county, and municipal health departments, boards of education, and nonofficial agencies employing a total of 10,351 nurses.

In the October, 1947, *Public Health Nursing*, median salaries for 1942, 1945, and 1947 are shown for three groups of nurses—directors, generalized supervisors, and generalized field nurses—in nonofficial agencies and in county and municipal health departments and for supervisors and school nurses of boards of education. These groupings represent nearly 7,000 of the total reported on, 260 directors, 528 supervisors, 5,109 generalized field nurses, and 998 school nurses.

For these groupings median salaries rose in the 5 years from 27 to 46 per cent, with the major increases between

1942 and 1945. The percentage increases, together with 1947 median salaries for the various groups, were as shown below.

It will be noted that, except for directors, the highest medians were reported by municipal health departments, a situation related in part to the size of the nursing staff. It will further be noted that the median for school nurses is higher than for generalized field nurses except in municipal departments although the school nurse's year is shorter than that of other nurses.

The published analysis also shows median salaries for all these groups classified by the number of nurses employed by agencies. As might be expected there is a fairly close correlation between salaries and size of agency which becomes inverse with agencies employing only one nurse or fewer than 5 nurses.

Detailed analyses for other occupational classifications and other agencies, chiefly state health departments, as well as by geographical areas have been made by the statistical service of the National Organization for Public Health

| | Directors | Generalized Supervisors | Generalized Field Nurses | School Nurses |
|-------------------------------|-----------|-------------------------|--------------------------|---------------|
| 1947 Median Salaries | | | | |
| Nonofficial Agencies | | | | |
| Official Health Departments | \$3,521 | \$2,921 | \$2,161 | \$ |
| Municipal | 3,169 | 3,338 | 2,527 | |
| County | 3,032 | 2,869 | 2,265 | |
| Boards of Education | | 2,931 | | 2,481 |
| Percentage increase 1942-1947 | | | | |
| Nonofficial Agencies | 33 | 46 | 34 | .. |
| Official Health Departments | | | | |
| Municipal | 27 | 34 | 34 | .. |
| County | 42 | 46 | 40 | .. |
| Boards of Education | .. | 34 | .. | 41 |

Nursing, which is prepared to furnish on request detailed data to public health administrators and directors of public health nursing.

Studied also in 1947, the first time since 1940, were salaries of non-nurse professional workers (*Pub. Health Nurs.*, Feb., 1948) in the agencies reporting on nurse salaries. Only 83 of the 41 agencies reported such workers numbering 209, more than half of which were about equally divided between state health departments and nonofficial agencies. The most numerous were nutritionists of whom 69 were reported.

The median salaries for the group of non-nurse professional workers, except for dental hygienists and physical therapists were nearly as high as those for generalized supervisors, but the small numbers involved may actually invalidate the significance of these figures. They should be studied in relation to size of agency, geographical location, etc.

Clerical salaries in the nursing services or departments were also reported (*Pub. Health Nurs.*, Mar., 1948). Perhaps the most significant single figure is the ratio of clerks to nurses. In all types of agencies 1,414 clerks were reported, representing one clerk to more than 7 nurses. County health departments reported one clerk to 3 nurses, nonofficial agencies one to 6, municipal health departments one to 9, and state health departments one to 12.

Median annual salaries for all clerical workers was \$1,816 ranging from \$1,676 for typists to \$2,111 for a miscellaneous group, including office managers, statistical clerks, etc. Of the 1,414 positions in this group, 520 were classified as clerks for whom the median salary was \$1,692.

LOCAL HEALTH DEPARTMENT SALARY STUDY

The June Journal (p. 867) reported

that a sampling study of local health departments is under way including 126 jurisdictions serving populations between 50,000 and 250,000. Questionnaires were sent to the health officers of these areas requesting information on the salaries paid to various professional groups, number of positions filled, and number of vacancies. After half of the questionnaires had been returned it became evident that the sample would not be large enough to assure statistical reliability. Reason: in most of the health departments there are many more vacancies than had been expected when the study was planned.

It was therefore decided to increase the sample to 100 per cent, covering all health departments in the population groups mentioned. Two hundred and sixty additional questionnaires are being mailed. It is expected that the results of the study will be available in the fall of 1948.

WESTCHESTER COUNTY MEDICAL SOCIETY RESOLUTION

The Westchester County Medical Society presented to the May meeting of the House of Delegates of the New York State Medical Society the following resolution on salary scales for public health physicians which was unanimously approved by the House of Delegates and referred to the Council for action:

WHEREAS: The health and welfare of the State of New York are dependent in many ways upon the satisfactory operation and performance of services provided through the New York State Department of Health, and

WHEREAS: Upon investigation it is evident that these services are suffering from a lack of essential medical personnel, and

WHEREAS: The Commissioner of Health is handicapped in making replacements of highly important specialists because of inadequate salary scales, and

WHEREAS: Present available salaries for public health and laboratory physicians in the State Department of Health are not com-

mensurate with incomes earned by physicians of like experience and training, and
WHEREAS: 48 out of 96 full-time medical positions in the State Department of Health remain unfilled as a result of the low salary scales now in effect, and

WHEREAS: Important public health programs and necessary research cannot be carried on because of these conditions, and

WHEREAS: These deficiencies threaten the health and welfare of the people of New York State, now therefore be it

RESOLVED: That the Medical Society of the State of New York respectfully petition the Governor of New York to take prompt action to rectify this situation by means of:

1. Upward salary scale revision.
2. The déléation of greater latitude to the Commissioner of Health to permit recruitment of personnel above salary scale minimums.
3. The simplification of civil service recruitment procedures as they pertain to medical personnel.

This resolution has added significance when it is remembered that New York is among the three or four states with the highest public health salaries in the country.

Sanitarian In-Service Training—Los Angeles County

The Bureau of Sanitation of the Los Angeles County Health Department has inaugurated an in-service training program for sanitarians. Classroom instruction amounts to 3½ hours per week. The classes are designed to continue over a period of 7 months. The list of subjects covered is comprehensive

in the field of environmental sanitation. In addition, such general topics as public health administration, public health statistics and epidemiology, and public health laws and law enforcement will be covered. Roy O. Gilbert, M.D., is the Health Officer of the Los Angeles County Health Department.

Public Health in Foreign Periodicals

GEORGE ROSEN, M.D., PH.D.

BEFORE World War II, the level of public health organization and effectiveness in Germany was comparable to that found in other countries of Western Europe or in the United States. One of the chief differences in organization as compared with such countries as Great Britain or the United States was the high degree of centralization in the German system. Apart from the changes in scope and structure resulting from the injection of political and racial ideologies, the functions performed by the German public health authorities were, on the whole, like those of our own.

The end of the war found the German public health system in a state of almost complete administrative disintegration. In the three years that have elapsed since then steps have been taken to reconstitute the administrative agencies necessary for effective public health work. Nevertheless, the political, economic, and social constellation has not been particularly favorable. The state of affairs is perhaps best described by the statement of an eminent German physician: "The average level of the health services in this country is already far below that which the older generation can still remember as having existed in times of even moderate prosperity."¹ Evidence is available, however, that strenuous efforts are being made to remedy this situation. A review of articles published in the *Ärztliche Wochenschrift* during the past six months reveals an awareness of pressing needs, a desire to evaluate and make use of whatever data are available, and a recognition that there is much to be learned

from public health practice in other countries.

PUBLIC HEALTH PROBLEMS

These trends are well exemplified in a paper by Otto Buurman surveying the public health needs and problems of present-day Germany.² These fall under three main heads: administration and personnel, control of communicable diseases, and nutrition.

Administrative reconstruction is hampered by the lack of uniformity resulting from the present zonal organization. Furthermore, within each state, the problem of centralization versus decentralization still remains to be solved. Buurman points out, for instance, that the central public health agency in the Soviet zone is actively rebuilding the necessary administrative organization, but that not infrequently this occurs in terms of a standpoint at variance with that which prevails in the British zone. For this reason, he strongly urges an interzonal exchange of ideas which will make possible uniformity of action in communicable disease control and other urgent health problems.

Effective action in dealing with these urgent matters is also handicapped by lack of adequately trained personnel. At the beginning of the war, medical education was accelerated and curtailed to provide the doctors and other personnel required for military purposes. With the prolongation of the war, further curtailment was found necessary. As a result, by the time the war ended a considerable deterioration in the quality of the German medical personnel had occurred. Buurman points up the urgent

need for repairing this damage, and insists that all physicians be given adequate training in bacteriological methods. In this connection, he states that other countries, particularly the United States, have left Germany far behind in this field. Such training is badly needed to control diseases such as typhoid fever, dysentery, diphtheria, and tuberculosis which are widely prevalent. Hand in hand with the training of personnel must go the creation of public health laboratories.

Problems of nutrition require urgent attention. Formerly German public health officials were concerned chiefly with food sanitation. Now, the advances made in the science of nutrition must be applied to benefit the German people. Here Buurman cites the technical excellence of the American food industry. In view of the close relation between nutritional status and resistance to disease, this author feels strongly that attention to problems of nutrition will go a long way in dealing with prevalent communicable diseases, particularly tuberculosis.

TYPHOID FEVER IN BERLIN

Study of the current German literature reveals that the problems presented above are seen in correct perspective. An instance in point is a report by Anders on typhoid fever in Berlin during the winter of 1946-1947.³ Typhoid fever has been endemic in Germany, between 3,000 and 6,000 cases occurring annually. Prior to the outbreak of the war, the number of cases in general tended to decline. Since 1939, however, the incidence of typhoid has been on the increase. During the war large-scale epidemics occurred, for instance, in Schleswig-Holstein and Hamburg.

In 1945 there was a large outbreak with about 15,000 cases in Berlin, but even after it was over a strikingly high number of fresh cases continued to be reported during 1946. In June, 1946,

there were 208 cases, in July 197, and in August 230, as compared with 151 reported cases in Berlin for the entire year of 1938. For a time it seemed that typhoid fever would become endemic in Berlin. To combat this situation a typhoid control campaign was organized in October, 1946, by the State Health Office.

The campaign lasted from October, 1946, to May, 1947, at which time all the districts of Berlin except four had been encompassed. The chief purpose of the campaign was to discover hitherto unknown typhoid carriers, and to check known carriers. Every reported case of typhoid was thoroughly checked to determine the source in the patient's environment. Diagnostic methods employed were examination of stool, urine, and bile, as well as examination of the blood for Vi-agglutination. In all, a total of 56 previously unknown carriers was found.

In his comments the author points out that certain sections of Berlin, which he calls "typhoid districts" are of particular concern to the health authorities. Living under indescribable hygienic and social conditions, the residents of these areas do not cooperate with the public health officers, and represent a threat to the city. Anders also calls attention to the defective training of many of the physicians in the typhoid wards of the hospitals, but adds that measures were taken to provide postgraduate lectures and demonstrations on typhoid fever. Shortly after the beginning of the campaign, the number of reported cases began to drop considerably. It is the author's opinion that, in addition to the seasonal and epidemiological factors involved, the drop in the reported cases was significantly influenced by the campaign against carriers.

VENEREAL DISEASE IN HAMBURG

The usual venereal diseases occur in Germany, but since 1940 little detailed

information on the incidence and prevalence of these conditions has been made available. For this reason the data provided by Hopf and Wennecke for Hamburg are of considerable interest.⁴ These authors state that while the impression has existed since 1939, in private and clinic practice, of an increase of the venereal diseases, such a rise was not numerically demonstrable for Hamburg. Recognizing the necessity of establishing as precisely as possible the magnitude of the venereal disease problem, the Hamburg Health Department decided to carry out on August 20, 1946, an enumeration of all venereal disease patients under treatment on that day. The interest of practitioners was secured by informing them that this enumeration would serve as a basis for medication procurement.

As a result, 5,064 patients were enumerated. Among these, 3,569 patients (72 per cent) were being treated for gonorrhea, and 1,379 (28 per cent) for syphilis (in various stages). There were 322 cases of primary lues, and 633 in the secondary stage. Of interest is the apparent relative increase in syphilis. Formerly, in Hamburg, lues accounted for 17 to 20 per cent of venereal disease while it now amounts to 25 to 30 per cent.

It had previously been estimated that there were 12,000 new cases annually in Hamburg. On the basis of the enumerated cases reported by Hopf and Wennecke, it was calculated that there is probably a minimum of 15,000 new infections annually. As the present population of Hamburg is 1.4 million, the estimated number of new infections represents an average annual increase of 1 per cent. In 1919 this percentual increase had been calculated at 3 per cent, and for the period from 1927 to 1934 at from $1\frac{1}{2}$ to 1 per cent. Consequently the authors conclude that while an increase in the incidence of the venereal diseases has occurred, the situation in

Hamburg is not particularly unfavorable.

DIPHTHERIA IN THE OBERBARNIM DISTRICT, 1942-1944

As in many other countries, German physicians are now evaluating the experiences of the war years. H. Malchin reports on the influence of diphtheria immunization on the epidemiological and clinical picture of diphtheria in the Oberbarnim District northeast of Berlin.⁵

Before the war diphtheria was already one of the major health problems. However, the incidence of diphtheria in various sections of the Reich varied greatly. During the 1920's and 1930's the course of diphtheria in Germany exhibits periodic fluctuations with epidemic peaks around 1917-1918, 1928-1929, and 1935-1937. The magnitude of the problem may be envisaged from the fact that the number of cases rose from 30,000 in 1926 to 293,000 in 1943. This increase was particularly marked after 1940, and was no doubt favored and facilitated by the large population movements of the war years. Furthermore, in 1942, an apparent change occurred in the clinical character of the disease. Toxic cases became more common, and the fatality rose. On the basis of these observations the health authorities of the Oberbarnim District, in March, 1942, decided to undertake a campaign of diphtheria immunization. This was done before any general policy had been established, and before any of the neighboring districts began to immunize.

The Oberbarnim District contained a population of 90,000. Of these, 19,000 were children ranging in age from 1 to 14 years; 92.08 per cent of the children received two injections of alum-precipitated toxoid. There was a drop in the number of cases among children, while cases among adults continued to rise. Cases did occur among immunized

children, but clinically these were mild. During the second half of 1944 there was a gradual rise in morbidity among the children who had been immunized. In view of this development, it was decided to Schick test all immunized children between the ages of 3 and 9 in the Oberbarnim District. This study included children from urban and rural environments. The testing began in the late summer of 1944, but had to be prematurely discontinued owing to the terminal events of the war. While admitting that his data were too small for definite conclusions, Malchin points out certain interesting observations. He reports that the percentage of urban children found to be Schick-positive was much higher than for the rural children, and attributes this to the better nutrition of the latter group.

MALARIA IN GERMANY

Interest in malaria has increased in Germany since the end of the war. In a recent article, Weyer discusses the present situation.⁶ Owing to a lack of exact statistical data there is considerable confusion regarding the origin, number, and significance of malaria cases in Germany at present. Weyer refers to the existence of endemic malaria in the Emden area, but states that by 1945 it had practically disappeared.

Nevertheless, since the end of the war the malaria situation in Germany has become worse owing to the development of autochthonous malaria in various areas. Malaria cases have appeared in Schleswig-Holstein, Lower Saxony, in the Rhineland, in Northern Württemberg, in the neighborhood of Karlsruhe, and in Mecklenburg, Pomerania, and Saxony. In 1946, through July, 662 cases were reported in Berlin, of which 220 were considered as having been acquired in the city. In 1947, Hohenner reported on 200 cases treated in Frankfurt a.d. Oder, of which 197 were newly acquired. In 1946, in Schleswig-Hol-

stein there were 470 cases; 119 were autochthonous. This malaria has been imported by returning German nationals who had acquired the infection abroad. In view of this situation, Weyer raises the question as to the probable future development of malaria in Germany.

The further existence and spread of malaria would require a sufficient number of infected humans, transmitting anophelines, and susceptibles. In addition, suitable environmental conditions are necessary. The considerable number of autochthonous cases indicates that these prerequisites are available in numerous localities. Yet it is extraordinarily difficult to make an epidemiological prognosis on the basis of the available information. The mosquito factor requires further study. Weyer believes that there are now more mosquitoes than before the war, especially in the cities, where they are able to breed more freely due to the destruction. Finally, the factor of climate must be studied. This factor would seem to be relatively unfavorable to mosquito development in Germany.

For the control of malaria and its epidemiological development, Weyer proposes constant supervision by the health authorities, intensive treatment of all malarious persons, control of mosquitoes by chemical means, and education of the public.

ORGANIZATION OF HEALTH AGENCIES

In order to deal with the problems discussed above, various semi-official health agencies have been organized. In 1947, organizations were created in Lower Saxony to combat venereal diseases and tuberculosis.⁷ Their chief purpose is to carry on health education in these fields.

BOOKS AND REPORTS

All reviews are prepared on invitation. Unsolicited reviews cannot be accepted. All books reviewed in these columns may be purchased through the Book Service.

The Neighborhood Unit Plan—Its Spread and Acceptance—Compiled by James Dahir. New York: Russell Sage Foundation, 1947. 91 pp. Price, \$1.00.

This selective bibliography with its interpretive comments is an important contribution to the urgent problems of city planning and urban housing in the years ahead. The subject presented, however, is broader and more fundamental to future family life than is indicated by the title.

The report should be of interest to lay and professional leaders alike, since it proposes an intelligent decentralization of all physical, governmental, social, recreational, and educational facilities in the interest of happy democratic living. The author marshalls an important array of evidence in support of the need of neighborhood planning and analysis, and interprets the material well. His method of presenting the references, illustrating the dramatic shifts in urban development, and building pictures from these authoritative sources, is unique and effective. The report serves a further useful purpose in bringing together in understandable fashion the varied experiences in neighborhood unit planning up to now and some of the obstacles to be over-

come. The last two chapters especially, which deal with American plans and projects and the neighborhood unit abroad, give an excellent view of new units in the making.

However, while the arguments are convincing, we need a better picture of how its development is to be accomplished; how long it will take; how it will work; and how it will build to its conclusion. How the obstacles are to be overcome might well be the subject of a later publication.

KENNETH D. WIDDEMER

A New Approach to Nutrition Services in State Health Departments—1946 Conference of the Milbank Memorial Fund. New York: Milbank Memorial Fund, 1947. 108 pp. Price, \$.75.

This compilation of papers, presented at the Round Table on Nutrition and Public Health, 1946 Conference of the Milbank Memorial Fund, deals with a subject of vital interest in public health. The experience and the vision of individuals prominent in public health and in the field of nutrition have been brought together in this volume to point a way for long needed direction to nutrition programs. It is suggested that the nutrition division in state health de-

partments needs at its head, a physician with special training in nutrition "to bring it to the necessary breadth of view." The functions of all health workers in the field of nutrition are thoughtfully discussed, and consideration is given to the needs of various population groups, such as industrial, maternal and infancy, and the school child. The record of the discussion is important, for, as is usual, the participants offered valuable suggestions in discussion which might never have been included in a prepared paper.

HAROLD R. SANDSTEAD

America's Needs and Resources—A Twentieth Century Fund Survey Which Includes Estimates for 1950 and 1960—By J. Frederic Dewhurst and Associates. New York: Twentieth Century Fund, 1947. 812 pp. Price, \$5.00.

This volume is an ambitious survey of the major economic and social trends in the United States, and on the basis of these it attempts to estimate the country's needs for 1950 and 1960, as well as the resources available to meet them. The project was broad in scope and required the efforts of a large group of experts in the various fields which the book covers.

The trustees and officers of the Twentieth Century Fund were well aware of the difficulties of a project of this kind at a time when world conditions were so unsettled as to make forecasts of any kind rather hazardous. Nevertheless, they had the courage to attempt to meet an important need of the times. Their purpose is well expressed in the Foreword by Evans Clark, Executive Director of the Fund. He says, "In authorizing and underwriting this survey the Trustees of the Fund have hoped to provide those who work and plan in each separate field, as well as those whose concern is the economy as a whole, with the bench

marks essential to any intelligent planning or appraisal. It is the Fund's hope that the educator, the clothing manufacturer, the cattleman, the wheat farmer, the Federal Reserve Board member, the labor unionist, the senator from this state or that, the president himself, as well as the average citizen who wants to know what this economy of ours is all about—that each of them can find in this volume some of the basic facts he needs to do his job more intelligently—and therefore more effectively."

Although no direct comparison was intended, this volume brings together and interprets masses of statistical material on economic and social trends similar to those embodied in the volumes *Recent Economic Changes in the United States*, published in 1929, and *Recent Social Trends in the United States*, published in 1933. It departs from these earlier projects in that a program of policies based upon the findings is avoided.

The book covers in some detail the facts on population trends; national income, expenditures and savings; consumer spending patterns and trends in terms of the major categories of consumption; capital needs and demands as well as capital formation; and government expenditures and their impact on the economy. In the discussion of capital requirements due attention is given to the needs arising from urban development and rural and regional development. The section dealing with resources and capacities considers both the human and natural resources as well as both our agricultural capacity and industrial capacity. Dealing as the volume does with the problems of the whole nation, it leans heavily on the statistical resources of many government agencies, and in fact, many of the contributions come from workers in these agencies. Throughout the volume one finds emphasis on the impact of the

war and more particularly how our sights were raised in many directions on the economic plane as a result of our amazing record of war production.

This book will be a valuable source of factual data for many years to come. It is liberally documented with numerous tables and charts both in the text and in the appendices.

Unfortunately world conditions have continued so unsettled and political and social trends have continued to vary so much from their pre-war pattern that many of the projections for 1950 made on the assumptions of two years ago will require considerable modification. For example, currently proposed military expenditures are much higher than were anticipated in this volume. This holds true also of our contributions for foreign reconstruction and restoration. Housing programs have fallen short for several reasons, such as the hesitancy on the part of private enterprise because of mounting construction costs and the lack of a consistent public housing policy. In the field of population, the projected figures are taken from the 1943 estimates of Thompson and Whelpton. The post-war birth rate has continued at a level much higher than was anticipated in these estimates, and immigration and repatriation of our citizens has further swelled the population. The effects of this unexpectedly large gain in population will be felt in many fields such as consumer demands and requirements, family life, education, and housing.

Of special interest to readers of this *Journal* is the chapter on Medical Care which was written by Margaret C. Klem and Helen Hollingsworth of the Bureau of Research and Statistics of the Social Security Administration. This chapter contains a wealth of statistical information on personnel and facilities for medical care, their number and distribution, incomes of the various professional groups in the medical and health

field, sources of hospital income, the major trends in health, medical care in relation to income and other factors, government expenditures for health, and prospective trends in the medical care field, particularly in relation to the future role of government. It is no fault of the authors that a good part of the literature in the field is relatively old, but they might have warned readers as to the limitations of the available data. Perhaps more should have been said with respect to the magnificent accomplishments in public health, especially the fine record made during the war years in the face of difficult conditions. In the matter of Selective Service findings, the authors accept rather lugubrious views which are far from justified.

In some respects the point of view in this chapter on Medical Care is not as objective as one would have liked to see it. Inevitably the authors of this chapter have been influenced by their official work and connections, but one cannot avoid the feeling that there is too much special pleading for the adoption of compulsory health insurance plans. Little notice is taken of the extension of medical group practice, of the extraordinary growth of private insurance plans covering hospitalization and medical care, of the marked increase in research in the field of cancer, heart disease, and other so-called degenerative diseases, which conditions will weigh heavily in the medical care needs of the future.

LOUIS I. DUBLIN

Child Care and Training—By Marion L. Faegre and John E. Anderson. (7th. ed.). Minneapolis, Minn.: University of Minnesota Press, 1947. 310 pp. Price, \$3.25.

In the seventh edition of this well known book the original plan has not been changed but the material has been brought up to date. This book de-

veloped out of the extension courses of the Institute of Child Welfare of the University of Minnesota. It is a sound and practical guide for study groups.

This book is also appropriate for individual parents. Three of the first chapters on the physical aspects of growth, including how children grow, general care, and children's diseases, are weak as compared with the rest of the text. The section on nutrition contains generalizations and suggestions which might be questioned. The section on height and weight has not been changed since the first editions of the book. The results of more recent studies on the measurement of growth and nutritional status could well have been mentioned.

The discussions on discipline, development and curiosity, social and mental development, emotional behavior, play, and the role of the family are particularly good and are concerned with children from infancy through high school. The chapter on sleep is to be recommended, as the authors recognize the importance of individual variations in sleep patterns and report the behavior and observations of large numbers of children.

The book contains an up-to-date bibliography on books dealing with the development and training of children, lists of toys and play material, and a number of reading lists for children.

RUTH RAATAMA

Factors Regulating Blood Pressure. *Transactions of the First Conference April 24-25, 1947, New York, N. Y. New York: Josiah Macy, Jr., Foundation.* 175 pp. Price, \$1.90.

In accordance with one of its established policies, the Josiah Macy Jr., Foundation has inaugurated a series of conferences on *Factors Regulating Blood Pressure*. This monograph is a record of the initial meeting which took place April 24-25, 1947.

It contains the text of 12 short intro-

ductory papers followed by a general informal discussion directly recorded at the time of the conference.

Members of the conference were selected on the basis of their past and continuing research interest in problems of the circulation. The papers represent original unpublished studies and elaborations of published data.

The papers cover a wide area, including discussions of the relation of the nervous system to hypertension, humoral factors in the pathogenesis of experimental and human hypertension, quantitative measurements of renal function, the prophylaxis of experimental hypertension and the treatment of human hypertension with low salt diets, low protein diets, renal extracts, tyrosinase, and quinones.

These studies bring up to recent date the wide variety of problems under discussion.

Especially valuable is the general informal discussion in which opposing points of view are freely expressed.

This monograph is highly instructive. It contains factual data and opinions of seasoned investigators which should be of considerable value to students of the circulation.

WILLIAM GOLDRING

The Blowflies of North America
—By David G. Hall, Baltimore, Md.: Monumental Printing Company, The Thomas Say Foundation, Entomological Society of America, 1948. 477 pp. Price, \$6.50.

Health officers, physicians, sanitary engineers, food inspectors, veterinarians, entomologists, nurses, in fact all those in any way concerned with preventive medicine will welcome the appearance of this excellent monographic treatment of a group of insects so important from a medical and veterinary point of view. In almost every quarter of the globe blowflies are in ill repute. True, they serve a useful purpose in helping to dispose of dead animal matter and in

cleaning up necrotic wounds. Many of them, however, are prone to leave animal carcasses and excreta and proceed with their germ-laden feet and mouth parts to contaminate fresh wounds or food.

Although this work is primarily systematic, the author follows the few pages on the history of classification of the blowflies with concise accounts of the part they play in the transmission of disease and the causation of myiasis. Up-to-date information on method of controlling blowflies is summarized in nine pages, and methods of collecting as well as preserving specimens are outlined.

The author has grouped the blowflies (family *Calliphoridae*) into 5 sub-families. Under each sub-family, keys are given to genera and species. Several new genera and many new species are described. The keys and text are very conveniently arranged. The discussion of each species includes synonymy, description of each of the stages of the more important flies, brief description of others, distribution, biology, habits, and economic importance. The summation of information on the biology and distribution is especially useful.

Those who have been grappling with blowfly problems for a number of years and have gathered a speaking or reading acquaintance with several of the scientific names of the species of medical importance will doubtless be much disturbed and perhaps disgusted to find so many of the old familiar handles replaced by new and not always euphonious ones. For instance, *Cynomyia cadaverina* becomes *Cynomyopsis cadaverina* and the "i" is knocked out of *Cynomyia*. When that generic name is used, *Lucilia sericata*, the common greenbottle fly becomes *Phaenicia*; the screwworm, *Cochliomyia americana* becomes *Callitroga americana*; and the false screwworm *Cochli-*

omyia macellaria also assumes *Callitroga* as a generic name, which from a pronunciation viewpoint we must admit is an improvement. Well, we know the desirability of following the approved rules of zoölogical nomenclature and we therefore bow in acceptance and just hope these new names and combinations are not soon changed again.

The volume is well and attractively bound in blue buckram with gold lettering. The paper is of excellent quality and the typography distinctly above the average. A well selected list of bibliographical reference is included. The index is excellent from the standpoint of valid names and synonyms, but reference to other information might have been more complete.

An examination of the 5 colored plates of flies and the 46 black and white drawings of heads, wings, and genitalia of adults, and principal structures of the larvae will convince the reader that the author is an artist as well as an entomologist. By the aid of these drawings and descriptions many who are not trained entomologists should be able to identify a number of the species of larvae involved in cases of myiasis. Accurate records of such cases are so desirable, however, that it would be well to send specimens to the U. S. National Museum for verification of identity.

Every medical library should have this valuable publication and every worker in the field of preventive medicine will find it a useful working tool.

FRED C. BISHOPP

American Building: The Forces That Shape It—By J. M. Fitch. Boston: Houghton Mifflin, 1948. 382 pp. Price, \$5.00.

James Emerson Fitch is an architect and planner of wide experience (including service with the T.V.A. and the Federal Housing Administration) and at present technical editor of the

Architectural Forum. He has written a book which will be of interest to the increasing number of members of our profession who realize that housing must be one of the central issues in the public health of the future.

Irrespective of any practical applications, this volume has much that will be of interest to the general reader. It is fascinating to follow the history of building from colonial days to prefabrication, to note the influence of technological factors—such as the sawmill and the brick kiln, the Franklin stove, the "Golden Leap" toward the control of space made in the construction of the Crystal Palace, the Brooklyn Bridge and the Eiffel Tower, the development of steel and of the welding process—upon structural possibilities. It is illuminating to trace the influence of men's ideals upon architecture to see how the Greek temple reflected the philosophy of Athens, the Gothic cathedral, the aspirations of the medieval church, and the functionalism of today, the empirical spirit of modern science. The series of plates, which include 177 individual pictures, are illuminating to the text and, in some cases, breath-taking in their beauty.

Mr. Fitch is intensely alive to the exciting possibilities of the newest advances of science and technology in the housing field; and allows himself even the luxury of such flights of fancy as the following: "To-morrow's sunlight will not enter to-morrow's buildings through holes punched in solid walls; rather it will be absorbed by the entire building, there to be filtered and mixed in the right proportions with artificial light to form a synthetic environment designed to our specifications. To-morrow's buildings may open and close automatically with the sun, like morning-glories; or, like sunflowers revolve slowly to keep their faces toward the sun."

Above all, this author is intensely

conscious of the broad social purposes of housing and planning; and it is this emphasis which will be most appealing to the student of public health. We can accept to the full his statement that "the function of American building must be the maintenance of those optimal environmental conditions essential to the health and happiness of the individual and to the peaceful and efficient development of American society."

C.-E. A. WINSLOW

Give Your Child a Chance—By Lenore Turner. *New York: Georgian Press, 1948.* 170 pp. Price, \$1.50.

This is a genuine effort on behalf of children. The author speaks directly and simply to mothers about the hundreds of everyday matters that come up in the life of infants and young children. She knows the mother's practical problems and also her fears and uncertainties. She tries to get the mother to understand the child's needs and feelings, and to relax while carrying out her program—avoiding tensions for both mother and child.

The book is readable and helpful and full of examples that make the teaching real. The contents cover the main problems that confused or anxious mothers ask questions about—management, fears, nervousness, and "bad habits," sex education, toilet training. The chapter on feeding is the longest in the book, but a good part of it has to do with the parent's attitude toward food and feeding, with recognizing the child's needs, the idea of letting the child indicate when he is hungry and when he has had enough, with changing diet and program, with getting the child to feed himself. That is, this chapter on feeding is in keeping with the entire book—guiding the child's emotional development is the central theme.

The book is addressed to fathers as well as to mothers. The discussion of

nursery schools and day nurseries tells the reader what to look out for, what to expect, and what choices one has to make. There is a usable index—that with one footnote reference represents the only concessions to the appearance of scholarship. Perhaps a few additional references to other useful books for those who will want to know more could have been included. But this is an excellent book that can be recommended without reservation. And it is a gratifying demonstration that people can be helped toward understanding and sound attitudes rather than be left to depend upon formal rules for meeting daily situations.

SIDONIE MATSNER GRUENBERG

Bacteriology — A Textbook of Microorganisms—*By F. W. Tanner and F. W. Tanner, Jr. (4th ed.). New York: Wiley, 1948. 625 pp. Price, \$4.50.*

In their preface the authors state that this is a textbook intended for those who are studying bacteriology for the first time, and the objective is to allow the student to build his structure on a broad biological basis of fundamental principles. This statement describes the book and its scope of usefulness.

In keeping with the expressed intent, nearly half of the book is devoted to the biology of bacteria, including their classification and relation to their environment. The applications of bacteriology that concern human welfare are treated in a general way and in orderly sequence.

The book presents several departures from the usual textbook treatment of bacteriology in that there is no consideration of individual bacterial species, and the etiological relationships of bacteria to human and plant diseases are presented in tabular form. More detailed considerations are left for subsequent advanced courses.

Discussions of culture media and methods, and of staining and other techniques, are omitted with the obvious intent to supply them from laboratory manuals. The teacher's attitude toward these omissions and condensations will depend on his approach to the subject. This book was designed for teaching in undergraduate college classes, not in medical schools. Considered from the viewpoint of its expressed purpose, of presenting bacteriology as biology, this reviewer likes it.

The text is well written and very readable, and the book is well made up by the publishers. Especially noteworthy are the sketches, in Chapter 1, of scientists prominent in developing bacteriology. The glossary of terms and literature citations should be useful.

JAMES E. FULLER

Canned Food Reference Manual. (3rd ed.) *New York: American Can Company, Research Division, 1947. 638 pp.*

Although the first edition of this volume was published only 8 years ago, in 1939, with a second edition in 1943, the numerous improvements and changes that occurred in commercial canning methods during the war made a third edition seem necessary. It presents the story of commercial canning from a general discussion of food preservation to a description of the commercial process. A general discussion of nutrition—what good nutrition is, what foods are necessary, what common nutritional inadequacies are, recommended dietary practices, and the nutritive value of commercially canned foods—and a review of regulations with specific reference to the Food, Drug and Cosmetic Act of 1938, complete the textual matter. A considerable portion of the volume is given over to an appendix consisting of numerous tables, giving the composition and nutritive value of the components of com-

mercially canned foods. A bibliography is also included. FRANCIS B. ELDER

Comparative Physiology — By Bradley T. Scheer, Ph.D. New York: Wiley, 1948. 563 pp. Price, \$6.00.

This is a new textbook intended for use in an advanced university course in comparative physiology. The author feels that comparative physiology should take its place beside comparative anatomy in the curriculum, since it serves to introduce basic principles by examining and interpreting variations in function in a wide variety of animal types.

The book represents a departure from previous texts in comparative physiology in that each chapter takes up the functional systems in a definite order for a single phylum. This arrangement makes it possible to compare functions in closely related organisms. A summary at the end of each chapter stresses the evolution in function within the phylum and the relations to other phyla.

The first chapter is devoted to a summary of fundamental physiological processes. To present this material in an abbreviated form without sacrificing accuracy is a difficult task. The author has done particularly well with it. The book is well documented throughout, numerous references in each section to original sources being readily available in footnotes. The great wealth of material presented and the arrangement of the material should attract the interest of physiologists and advanced students in zoölogy.

C. W. HAMPEL

Legal Aspects of Milk Sanitation — By James A. Tobey, Dr.P.H., LL.D. (2nd ed.). Washington: Milk Industry Foundation, 1947. 133 pp. Price, \$5.00.

The first edition of this book, published in 1936, listed and interpreted over 300 court decisions relating di-

rectly to milk control with pertinent discussion and quotations from judicial opinions. The present revision brings the work up to date, including about 100 additional decisions that have been handed down since 1936 and other new material. It is concerned primarily with public health control of milk and milk products. The legal aspects of price fixing are not covered except by a brief review of decisions handed down by the United States Supreme Court.

The purpose of the book is given in the preface as "an attempt to restate in lucid terms the constitutional, administrative, public, and private law in this country as it has been and is being applied to the production, handling, processing, distribution, and sale of milk and dairy products. The book is not intended as a substitute for an attorney, but as a practical guide to the established law on this important subject. For this purpose it has been extensively documented, so that those who are faced with specific problems may have sources of further information."

With many years of experience in this field and unusual ability as a writer, the author has fulfilled the above purpose admirably. The text is concise but is adequate for a general understanding of the law on all aspects of milk control. Case references are given page by page in footnote citations and also at the end of the book in a table of cases arranged according to states. A good general bibliography and an adequate index are included.

Although written primarily as a source of information for the milk industry, this book is equally suitable for the use of health officers and others who must deal with the administration and enforcement of milk sanitation regulations. Although not very strongly bound, the book is well printed, conveniently arranged, and otherwise of satisfactory format. ROY J. MORTON

BOOKS RECEIVED

Listing in this column acknowledges the receipt of books and our appreciation to the senders. Space and the interests of readers will permit review of some, but not all, of the books listed.

- COMMUNICABLE DISEASES. Nina D. Gage, R.N., and John Fitch Landon, A.B., M.D. (5th ed.). Philadelphia: F. A. Davis, 1948. 541 pp. Price, \$4.00.
- THE DIABETIC'S HANDBOOK. Anthony M. Sindoni, Jr., M.D. New York: Ronald Press, 1948. 194 pp. Price, \$3.00.
- DIAGNOSTIC PROCEDURES FOR VIRUS AND RICKETTSIAL DISEASES. Thomas Francis, Jr., M.D., Chairman, Committee on Diagnostic Procedures for Virus and Rickettsial Diseases. New York: American Public Health Association, 1948. 347 pp. Price, \$4.00.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

RAYMOND S. PATTERSON, PH.D.

Warmly Recommended Reading
 —Based, for a change, on realities a practical dental health plan for Baltimore children is set in motion. There should be some suggestions for you— if you have any concern whatever about the commonest of all physical defects— in this forward-looking move.

ANON. A Dental Care Program for Baltimore's School Childrep. Baltimore Health News 25, 5-6:26 (May-June), 1948.

Alcoholics Non-Industrious—Alcoholism is a very great public health problem, asserts this student who tells what industry might do about reclaiming its drunks during the two to ten years they take to progress from serious

drinker to full-blown souse. The cost is \$90 to \$140 per lush reclaimed.

BACON, L. R. Alcoholism in Industry. Indust. Med. 17, 5:161 (May), 1948.

Strains of Influenza A—Vaccines, which were effective against earlier influenza outbreaks, failed to protect the vaccinated during the 1947 visitations, in so far as the experience of 13 industrial establishments goes. But, don't be too discouraged: probably we'll have more potent vaccines in the future, asserts the reporter.

BAETJER, A. M. Results of Influenza Vaccination in Industry During the 1947 Epidemic. Indust. Med. 17, 5:171 (May), 1948.

This Seems Reasonable—After a three year study, a commission concludes that influenza A and B are endemic infections which periodically erupt in epidemics. Between eruptions the virus is transferred from unrecognized case to unrecognized case.

COMMISSION ON ACUTE RESPIRATORY DISEASES, FORT BRAGG, N. C. Endemic Influenza. *Am. J. Hyg.* 47, 3:290 (May), 1948.

Go Slow, They Urge—Streptomycin cannot be considered a cure for tuberculosis at present, assert two Doubting Thomases. More controlled experiences are needed before accepting the drug as more than incompletely retardant of the infection in man. The paper's discussant seems to imply that the writers erected a sizable straw-man to bowl over.

CORPER, H. J. and COHN, M. L. Various Phases of the Use of Streptomycin in Tuberculosis. *J. A. M. A.* 137, 4:356 (May 22), 1948.

Rats Is Rats—For what it's worth to you, here is a statistic: a third of all roof rats of San Antonio carried typhus antibodies, while a half or more of the brown rats were positive.

DAVIS, D. E. Observation on Rats and Typhus Fever in San Antonio, Texas. *Pub. Health Rep.* 63, 21:783 (June 11), 1948.

"An Idea Whose Time Has Come"—Outlined in this useful paper is the plan for a rural-hospital-health-center to be created under the Hospital Construction Act. You had better familiarize yourself with this example of what can be done.

DAVIS, G. L. The Hospital as a Community Health Center. *Pub. Health Nurs.* 40, 6:311 (June), 1948.

"Study, Decision—and Action"—Don't miss this. The chairman and four participants discuss the National Health Assembly. We are due to hear about that gathering for months to come, but you'll profit by this early report.

EWING, O. R., *et al.* Essentials for National Health. *Survey Midmonthly*, 84, 6:185 (June), 1948.

Sanitizing Agents—One quote is offered on the chance it will tell you whether you will profit by reading the whole paper: "If the alkalinity of the detergent is sufficiently high to saponify fat, the resulting soap will inactivate the cationic quaternary ammonium compound with resultant loss in bactericidal activity."

GLASSMAN, H. N. Surface Active Agents and Their Application in Bacteriology. *Bact. Rev.* 12, 2:105 (June), 1948.

Carriers are Responsible—Polio virus leaves the patient through secretions of the mouth and nose and by the feces. Direct contact with infected persons rather than any widespread neighborhood factor is the usual source for the spread, these researchers conclude.

GORDON, F. B., *et al.* Laboratory Study of the Epidemiology of Poliomyelitis. *J. Infect. Dis.* 82, 3:294 (May-June), 1948.

"Serious Deficiencies Exist"—Having ascertained the needs, the Academy of Pediatrics, collaborating with the Public Health Service and the Children's Bureau, has embarked upon an ambitious attempt to better the distribution of child health services for *all* children. May they succeed beyond their most ambitious dreams!

HUPBARD, J. P., *et al.* Health Services for the Rural Child. *J. A. M. A.* 137, 4:337 (May 22), 1948.

What's a Cured Cancer Worth?—Cancer detection centers are an expensive undertaking, outside the realm of practicability for the average community. The National Cancer Institute has set up a demonstration unit at Hot Springs to see what parts can be salvaged from the idea that might be put to use locally.

KOPLIN, A. N. Objectives and Program of the Arkansas Cancer Detection Project. *Pub.*

Health Rep. 63, 25:813 (June 18), 1948.

Tampering With Personality— This you must read. It's about the nurse's contribution to mental health, but what the writer says to nurses applies equally to most of the rest of us. His introductory statements about the practicability and applicability and durability and clarity of ideas is not to be missed.

LEMKAU, P. V. What Can the Public Health Nurse Do in Mental Hygiene? Pub. Health Nurs. 40, 6:299 (June), 1948.

Good Samaritans Please Note— Blood donors recovered their hemoglobin, red cell, and serum protein levels quickest when their diets furnished 90 gm. of protein daily. One quart of milk, an egg, two servings of meat and one of cheese or legumes produced the 90—and a little gain in weight.

LEVERTON, R. M., *et al.* Blood Regeneration in Women Blood Donors. J. Am. Dietet. A. 24, 6:480 (June), 1948.

Artificial Respiration— Health workers with a yen for first aid will want this exhaustive report on "suck and

blow" and other respirators, for their clipping files.

MOTLEY, H. L., *et al.* Intermittent Positive Pressure Breathing. J. A. M. A. 137, 4:370 (May 22), 1948.

"Needs Must When the Devil Drives"—On May 7, London commemorated the centenary of the appointment of Sir John Simon, first Medical Officer of Health for the city. You need the historical information in the story of his appointment. Fear of approaching cholera was the principal cause.

UNDERWOOD, E. A. The Centenary of British Public Health. Brit. M. J. No. 4557 p. 890 (May 8), 1948.

He's Against Wholesale Medication—Of the contacts of early syphilis cases brought in for examination, slightly less than half were found to be infected. The proposal that *all* contacts be treated seems unwise, in the face of these findings, says the writer.

VON WERSSOWETZ, A. J. The Incidence of Infection in Contacts of Early Syphilis. Ven. Dis. Inform. 29, 5:132 (May), 1948.

Greetings from the Public Health Association of Brazil

The American Public Health Association is in receipt of the following letter from Dr. Oswaldo L. da Costa, the Executive Secretary of the Sociedade Brasileira de Higiene of Rio de Janeiro. Through the columns of the *American Journal of Public Health* it is shared with North American colleagues to whom it is addressed.

"The Sociedade Brasileira de Higiene, a National Organization of Public Health workers, considers this opportunity very appropriate to address its North American colleagues through the American Public Health Association.

"The factors that determined the creation of our society are the same that prompt us now to send this message: Association of

ideas and efforts for the progress of Public Health.

"The aims of all workers in the field of health protection are not limited by national boundaries and are free from individual or group prejudices.

"This assertion has more power and more truth for those who follow the new and successful road of the aptly called 'Good Neighbor Policy.'

"We want to add to the many facts that day by day are strengthening the approach of our governments and people this letter from the doctors, engineers, nurses and other affiliates of the Sociedade Brasileira de Higiene to the American Public Health Association.

"The American Public Health Association will surely make known to all its associates this message of friendship and hope for ever-increasing cooperation."

ASSOCIATION NEWS

SEVENTY-SIXTH ANNUAL MEETING
AMERICAN PUBLIC HEALTH ASSOCIATION
BOSTON, MASS., NOVEMBER 8-12, 1948

NOMINATIONS FOR THE GOVERNING COUNCIL

In accordance with the By-laws of the Association, the Nominating Committee for Governing Council Members consisting of one Fellow elected by each Section and a Chairman appointed by the Executive Board, reports the following nominations for the Governing Council. The Chairman of the Committee is George T. Palmer, Dr.P.H., Consultant in Public Health Administration with the California State Department of Public Health. The other members are: J. Lloyd Barron, Engineering Section; Samuel R. Berenberg, M.D., Maternal and Child Health Section; Frank C. Cady, D.D.S., Dental Health Section; Marion H. Douglas, R.N., Public Health Nursing Section; Marietta Eichelberger, Ph.D., Food and Nutrition Section; J. William Fehnel, Industrial Hygiene Section; Ruth E. Grout, Ph.D., School Health Section; Henry E. Meleney, M.D., Epidemiology Section; Lucy S. Morgan, Ph.D., Public Health Education Section; Hugo Muench, M.D., Vital Statistics Section; Thomas F. Sellers, M.D., Laboratory Section; and E. V. Thiehoff, M.D., Health Officers Section.

The By-laws provide that "upon the petition of twenty-five Fellows, the Nominating Committee shall add the name of any Fellow to the nominees selected by it, provided such petition is received not less than thirty days before the Annual Meeting."

The terms of ten elective Councilors will expire at the time of the Boston Annual Meeting. The ten nominees receiving the highest number of votes cast by the Fellows present and voting at the Annual Meeting will be declared elected to fill the three year term expiring in 1951.

New Orleans, La.

PROGRESS IN THE MERIT SYSTEM SERVICE

The Merit System Service of the Association has more than tripled its output during the past year as is revealed in a recent report to the Executive Board. Thirty-three states and nine cities have used the examinations prepared by the Merit System Service. In addition, schools of public health nursing, schools of sanitary engineering, visiting nurse associations, the U. S. Public Health Service and state licensing or registration boards are using these examinations.

Descriptive of the activity of the staff on the 5th floor at 1790 Broadway, New York, is the report for the month of May, 1948. Twenty-seven examinations were prepared for 6 states and delivery of examinations was made to one school of public health nursing. Three states ordered 19 examinations for future delivery. There are orders on hand for 61 examinations for 9 states and 23 exami-

nations for the U. S. Public Health Service.

To show the widespread use of the examinations, lists were prepared as of May 31, 1948. Seven states have ordered written examinations for administrative health officers, and two cities have used examinations for similar classes. The U. S. Public Health Service is using written objective-type examinations prepared in coöperation with the Merit System Service for the selection and promotion of commissioned officers. One state is planning to use the examinations for the selection of medical officers for promotion within the state health department. The states which have used examinations for administrative health officers are as follows:

Administrative Health Officers

California
Colorado
Illinois
New York
Oklahoma
South Dakota

Examinations for the selection of laboratory personnel have been delivered to 16 states as follows:

Laboratory

| | |
|-------------|----------------|
| Alabama | Nevada |
| Georgia | North Carolina |
| Illinois | Oklahoma |
| Kentucky | Rhode Island |
| Louisiana | South Dakota |
| Maryland | Utah |
| Mississippi | Vermont |
| Missouri | West Virginia |

Twenty-one states have ordered examinations in environmental sanitation. One state is using an examination for licensing sanitary inspectors and a school of sanitary engineering used an examination for students of sanitary engineering. The Public Health Service is now using examinations for the selection and promotion of sanitary engineers. The states using examinations in environmental sanitation are listed.

The most extended use of written examinations prepared by the Merit System Service is in the field of public health nursing. Examinations have been delivered to 30 states as well as to

Environmental Sanitation

| | |
|------------|----------------|
| California | Massachusetts |
| Colorado | Mississippi |
| Florida | Missouri |
| Georgia | Nebraska |
| Idaho | Nevada |
| Illinois | North Carolina |
| Iowa | Oklahoma |
| Kentucky | South Carolina |
| Louisiana | South Dakota |
| Maryland | Utah |

schools of public health nursing, visiting nurse associations and the U. S. Public Health Service. The states are listed below.

The use of written objective examinations as one of the devices for selecting public health personnel is on the increase and indicates a trend in personnel practices. A health agency is considering using written objective examinations for determining knowledge in the general field of public health as a guide to in-service training. The Merit System Service is developing short illustrative examinations for use at the annual meeting. Inquiries regarding the examination services are invited.

APPLICANTS FOR MEMBERSHIP

The following individuals have applied for membership in the Association. They have requested affiliation with the sections indicated.

Health Officers Section

Joseph M. Bistowish, M.D., County Health Dept., P. O. Box 491, Gainesville, Fla., Asst. Health Officer, Alachua County
L. R. B. Centanni, M.D., Box 128, Thibodaux, La., Director, Lafourche Parish Health Unit

Sidney Cobb, M.D., Nashoba Health Unit, Central Ave., Ayer, Mass., Director
Harold O. Hunt, M.D., Town Hall, Falmouth, Mass., Inspector, Falmouth Board of Health
George Kraus, M.D., 51 Blaine St., Fairfield, Conn., Health Officer, Town of Fairfield

- Juan Moroder, M.D., M.P.H., Escuela de Salubridad, 9 de Julio, 3467, Santa Fe, Argentina, S. A. Professor of Public Health Administration, School of Public Health, National University of the Litoral
- Gordon M. Parrott, M.D., 1023 N. Tacoma Ave., Tacoma, Wash., Asst. Director, Tacoma & Pierce County Health Depts.
- W. M. Singleton, M.D., Court House, Room 303, Portsmouth, Ohio, County Health Commissioner, Scioto County Board of Health
- Joseph H. Stickler, M.D., M.P.H., Route 5, Box 993, Hanford, Calif., Kings County Health Officer
- Albert E. Thoms, M.D., C.M.D.P.H., Leeds & Grenville Health Unit, Brockville, Ontario, Canada, Director
- Myron G. Tull, M.D., M.P.H., 426 E. Lake Ave., Baltimore 12, Md., Administrative Health Officer, City Health Dept.

Laboratory Section

- Virginia D. Allen, M.S., State Laboratory of Hygiene, M. I. Bldg., Madison, Wis., Bacteriologist
- Louise Barney, 2227 Ellis Ave., Boise, Idaho, Senior Bacteriologist, State Dept. of Public Health
- Seymour A. Greenspon, A.M., 201 College Ave., Columbia, Mo., Instructor in Medical Bacteriology and Preventive Medicine, Univ. of Missouri
- Russell R. Harrison, 209 Center Drive, N.H.A. 1, Honolulu 50, T.H., Bacteriologist and Asst. Epidemiologist, District Medical Office, Preventive Medicine Section, Pearl Harbor, T.H.
- Floyd A. Martin, M.D., 4 McAlester Hall, Columbia, Mo., Professor of Bacteriology and Preventive Medicine, School of Medicine, Univ. of Missouri
- A. Kealy Mayes, City Health Dept. Laboratory, 2013 Commerce, Dallas, Tex., Laboratory Director
- Francis Pattison, Caro State Hospital for Epileptics, Caro, Mich., Bacteriologist
- Helen Schmidt, 4218 Geneva St., Pittsburgh 1, Pa., Student, Univ. of Pittsburgh
- Milton Segalove, Ph.D., 10717 Venice Blvd., Los Angeles 34, Calif., Bacteriologist, Bio-Science Laboratories, Inc.
- Charles Symon, M.D., Benesova 10, Brno, Czechoslovakia, Asst. Dept. of Hygiene and Bacteriology, Medicine Faculty, Brno
- Peter Vogel, M.D., 51 East 90th St., New York 28, N. Y., In charge, Rh. Testing Laboratory, Bureau of Laboratories

Engineering Section

- Charles G. Caldwell, M.S., 554 E. Garcia,

- Santa Fe, N. M., Director, Division of Sanitary Engineering and Sanitation, State Dept. of Public Health
- Ray L. Derby, Terminal Annex, P. O. Box 3669, Los Angeles, Calif., Principal Sanitary Engineer, Los Angeles Dept. of Water and Power
- Robert E. Mytinger, 136 South Canon Drive, 106, Beverly Hills, Calif., Student, School of Public Health, Univ. of California
- Donald L. Truax, 101 California St., San Francisco 19, Calif., Consulting Sanitarian, California Packing Corp.
- Thomas N. Uffelman, 1012 18th Avenue South, Nashville 4, Tenn., Trainee, Davidson County Health Dept.

Industrial Hygiene Section

- M. N. Rao, Dr. P.H., 110 Chittaranjan Ave., Calcutta, India, Asst. Professor in Physiological and Industrial Hygiene, All India Institute of Hygiene and Public Health

Food and Nutrition Section

- Margaret P. Zealand, 19 W. State St., Trenton 8, N. J., Nutritionist, State Dept. of Health

Maternal and Child Health Section

- Helen E. Hestad, 2732 Harriet Ave., South, Minneapolis, Minn., Consultant in Maternal and Child Health, Bureau of Public Health Nursing, City Health Dept.
- Wallace S. Trowbridge, 1116 Denver, Boise, Idaho, Special Investigator, State Dept. of Public Health

 Charles V. Wynne, M.B.A., Waterbury Hospital, Waterbury 61, Conn., Superintendent

Hotel Reservations at Boston

Members are asking which is the "Headquarters" hotel for the Boston Annual Meeting. The answer is that no one hotel has been designated headquarters for delegates because Boston's hotels, though numerous, are not large.

A Housing Bureau is being operated for the Association by the Boston Convention Bureau. We are asking members to select their own hotel from among those listed on page 1178. The application should be carefully filled in and mailed to:

The Housing Bureau
 Boston Chamber of Commerce
 80 Federal Street
 Boston, Mass.

Convention activities will center largely in Mechanics Building. We rearrange the list of hotels below to show you their location with relation to Mechanics Building. No. 1 is nearest, 2 next in order of distance, and so on.

- | | | |
|-----------------------|-------------------------|----------------------|
| 1—Hotel Minerva | 6—Hotel Statler | 13—Hotel Kenmore |
| 2—Copley Square Hotel | 7—Hotel Bradford | 14—Hotel Braemore |
| 3—Copley Plaza Hotel | 8—Hotel Touraine | 15—Hotel Bostonian |
| 4—Hotel Lenox | 9—Hotel Puritan | 16—Hotel Bellevue |
| 5—Hotel Gardner | 10—Hotel Somerset | 16—Hotel Manger |
| 5—Hotel Hemenway | 11—Hotel Myles Standish | 16—The Parker House |
| 5—Hotel Vendome | 12—Hotel Sheraton | 17—Hotel Continental |

Single rooms are few and are hard to obtain. Rooms for double occupancy are strongly recommended. There is no question about the ability of Boston's hotels to accommodate the delegates to the Annual Meeting, but the Housing Bureau and the Local Committee ask the coöperation of the membership in seeking double rather than single room accommodations.

A.P.H.A. membership application blank on page XXV

THE 76TH ANNUAL MEETING

Boston, Mass., November 8-12, 1948

Graduate Veterinarian, experienced in disease control work and private practice, desires position in industry and/or public health field. Write Box V-4, Employment Service, A.P.H.A.

Biological and Physical-Chemist, Ph.D. available soon, for Research or Teaching, extensive experience in pharmacology, pharmaceuticals, biologicals, bio-assays. Former university professor, former head, development department of large pharmaceutical manufacturer; 60 publications, many in medical research; books. Executive ability and experience. Age: 35; married; children. Seeks responsible position, educational institution or hos-

pital laboratory. New York Metropolitan area preferred. Answer Box L-2, Employment Service, A.P.H.A.

Sanitary Engineer—6 years' experience in the field of public health engineering with Sanitary Corps, Federal and private agencies. M.S. degree in Sanitary Engineering. East preferred. Write Box E-5, Employment Service, A.P.H.A.

Health Educator, B.S., M.A., Ed.D.; 10 years' experience with public schools and colleges. Now doing teacher training in large state university and acting as consultant to school administrators and teachers. Seeks opportunity in public school health program or combination of health and physical education in either public schools or college teacher-training. Write Box A-25, Employment Service, A.P.H.A.

Public Health Administrator, M.D., Dr.P.H. Twelve years' experience in teaching of public health and preventive medicine in various medical schools. Experience as director of school health in a public school system. Eight years' experience in official and voluntary agencies and armed forces. Midwest preferred. Currently employed, but seeking challenging position. Write Box C-2, Employment Service, A.P.H.A.

Dentist—Thirty years' experience in clinical and 5 years' experience in public health hospital administrative work. Interested in dental opening (South and Southwest preferred) with or without clinical responsibilities. Write: Box D-2, Employment Service, A.P.H.A.

Opportunities Available

WANTED—(a) Public health administrator; residential town of 65,000; competent organizer required; Middle West; minimum \$7,500. (b) Public health dentist; administrative position; voluntary health agency supported by Community Chest with children's dental clinics located in different parts of city and suburbs; Eastern metropolis. (c) Public health physician for position with preventive medicine department of large industrial company; East. (d) Two student health physicians and, also, dentist, to join staff of student health department, university having enrollment of 12,000 students; West. (e) Young woman physician; student health department, young women's college; New England. (f) Director of school health service; metropolitan area; East; \$8,000. PH8-1 Medical Bureau (Burnice Larson, Director), Palmolive Building, Chicago 11.

WANTED—(a) Statistician to direct division of vital statistics, state department of health; \$5,100.

(b) Bacteriologist, M.S. degree with two years' experience in public health laboratory work required; municipal department of health; Middle West. (c) Health educator; newly created position, municipal health department, middle western town of 150,000. (d) Sanitary engineer; division of engineering and sanitation; county department of health serving population of 300,000. (e) Superintendent of sanitation; city health department; 150 employees; Southern city, 200,000. (f) Health educator to work with colleges and educators; preferably one who has taught health education in a teachers college; willing to travel; East. (g) Sanitary engineer to direct department serving population of 7,000,000; experience in water and malarial control required; M.A. degree and public health background essential; South America. (h) Sanitary engineer qualified to handle malaria control work; training in bacteriology required; operation of large industrial company in Africa. (i) Instructors; department of public health and bac-

teriology; opportunities for research; state university; West. PH8-2 Medical Bureau (Burneice Larson), Palmolive Building, Chicago 11.

WANTED—(a) Orthopedic nursing consultant; duties consist of developing and organizing adequate consultation service in orthopedic nursing; degree and graduate training in public health nursing required; university medical center; Mid-south. (b) Supervisor of public health nursing; county health department; generalized program; headquarters in city of 45,000; East. (c) Coordinator of public health nursing; duties consist of directing public health program for student nurses; university appointment; East. (d) Student health nurse;

young women's college; duties consist of taking charge of boarding school group of approximately 60 students and 15 faculty members; no responsibilities in connection with day school of 300 students except in matters of consultation; program directed by school doctor; well equipped infirmary; university medical center; opportunity for continuing studies. (e) Public health supervisor; generalized program; Pacific Northwest. (f) Public health nurses of supervisory caliber for executive positions in Latin America; knowledge of French, Spanish, or Portuguese desirable; interesting appointment. PH8-3 Medical Bureau (Burneice Larson, Director), Palmolive Building, Chicago 11.

Opportunities Wanted

Physician well qualified as health educator; B.S., M.D., and Master of Health degrees; several years, director of university health service where he has carried a rather heavy teaching load; recommended as an exceptionally fine teacher, clear thinker about problems of education and student welfare, able to stimulate students to high degree of activity; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Dentist experienced in public health work; several years, private practice limited to children's dentistry; past six years public health dentistry; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Sanitarian; Degree in Civil Engineering; five years, sanitary engineer, county health department; six years, director, rural sanitation, state department of health; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Statistician; M.S. in Mathematical statistics; M.S.P.H. in public health statistics; year's research

experience; five years, statistician with public health organization; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Health educator; B.S., M.S., and Ph.D. degrees; several years, instructor in biology, bacteriology and health; state university; three years, public health educator, city and county health department; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health nurse executive; M.S. degree, health education and public health; six years, executive secretary, county tuberculosis association; seven years, director, metropolitan public health nursing association; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

Public health physician; degrees, Eastern schools M.P.H. Johns Hopkins; twelve years' administrative experience in public health medicine; for further information, please write Burneice Larson, Director, Medical Bureau, Palmolive Building, Chicago 11.

NEWS FROM THE FIELD

NATIONAL LOCAL HEALTH UNITS PROGRAM TAKES ANOTHER STEP

On June 30, in New York, a newly appointed 16 member Interim Steering Committee of the National Advisory Committee on Local Health Units met for an all day conference to plan the program of the body for the coming months. The Chairman of the meeting was Philip R. Mather, President of the National Health Council, which is furnishing the secretariat and operating expenses for the National Advisory Committee.

As indicated in earlier issues of the Journal,¹ this National Advisory Committee grew out of the Princeton Conference when for the first time a large body of citizen and voluntary health agencies picked up the ball that had up to then been carried by the A. P. H. A., with the support of the American Medical Association and the Association of State and Territorial Health Officers.

Among the facts brought out at the June 30 meeting were that the National Advisory Committee now includes representatives of 45 national agencies, 25 of them citizen agencies such as Parent Teacher Associations, Lions, and National Grange, and 20 of them voluntary or professional health agencies; that 8 Bulletins on Local Health Units have been sent to a mailing list of some 450 agency executives, representatives, and house organs, state health officers, and a selected list of interested individuals, libraries, and publicity media. The 5-State Regional Conference² recently held in Indiana was also reported on, as were many of the current developments in the various states—the newly organized state-wide public health committees of Washington and Wisconsin for example, the organization of the new multi-county units in Colorado and In-

diana, the very active campaign of the Lions International, which includes a half-day forum on local health units at the annual international meeting of this organization in New York, July 26-29; excellent material published in such journals as the *Junior League Magazine*, the *Lion*, the *Bulletin of the National Congress of Parents and Teachers*, and others. Activities of such varied organizations as County Medical Societies and their Woman's Auxiliaries, the American Association of University Women, the League of Women Voters in Virginia, Utah, Colorado, Iowa, and many other states, were reported.

The favorable action of the House Committee on Commerce and Labor on the PTA sponsored Public Health Services Bill of 1948 and the bright hopes for its passage in the special session of the 80th Congress, if called, or in the first session of the 81st, were also reported. These activities were reviewed by the agency representatives and by John W. Ferree, M.D., Associate Director of the National Health Council.

Haven Emerson, M.D., whose study, *Local Health Units for the Nation*, published in 1945, started this activity, pointed out the significance of the resolutions of the National Health Assembly³ and of the National Conference on Family Life⁴ in furthering the aim of covering the entire populace with full-time medically directed local health departments.

Reginald M. Atwater, M.D., Executive Secretary of the American Public Health Association told the committee that only through local community recruitment of public health workers could present personnel shortages be overcome.

The discussion of problems and the program for the future was under the

chairmanship of James Stone, Director of Program Development of the National Tuberculosis Association. Among the interim activities planned for the future were:

A meeting of the entire National Advisory Committee in the fall of 1948 to organize on a permanent basis and to develop a long term program.

A five State Rocky Mountain Regional Conference in Salt Lake City in October.

Continuation of the *Bulletin on Local Health Units* as an activity of the National Advisory Committee and in a more attractive format. Its primary purpose is to serve as a medium of information and of ideas for committee member agency house organs or journals.

Preparation of a pamphlet that would tell in brief and simple form what a local health department is, what benefits a community may expect from it; and how a community organizes itself to secure a unit or to make its existing one more effective.

The members of the Steering Committee are:

American Cancer Society, Edith M. Gates, Health Education Specialist

American Medical Association, A. J. Chesley, M.D., Minnesota State Health Commissioner

American National Red Cross, Ruth B. Freeman, R.N., Administrator of Nursing Services

American Public Health Association, Haven Emerson, M.D., Chairman, Subcommittee on Local Health Units

Association of State and Territorial Health Officers, Vlado A. Getting, M.D., Massachusetts State Health Commissioner

Congress of Industrial Organizations, Leo Perlis, National Director, CIO Community Services Committee

Lions International, Lee A. Rademaker, M.D., International Director

National Congress of Parents and Teachers, Mrs. L. W. Hughes, President

National Council of Negro Women, Mrs. Bertell Collins Wright, Health Education Secretary, Essex County (N. J.) Tuberculosis League

The National Grange, Lloyd C. Halvorson, Economist

National Health Council, John W. Ferree, M.D., Associate Director

National Organization for Public Health Nursing, Dorothy Rusby, R.N., Assistant Director

National Social Welfare Assembly, David H. Holbrook, Assistant Director

National Tuberculosis Association, James G. Stone, Director, Program Development

Young Mens Christian Association, National Council, H. T. Friermood, Secretary, Health and Physical Education

Mr. Mather was elected Chairman pro tem. of the National Advisory Committee and Martha Luginbuhl, Research Assistant of the Subcommittee on Local Health Units, Secretary pro tem. They will hold office until the organization meeting of the National Advisory Committee.

NURSES CONSIDER ONE NATIONAL ORGANIZATION

Nurses marked a milestone recently in their search for a form of organization that will best serve both nurses and "consumers" of nursing. The effort had its beginnings in 1939, and has gone through several phases, including a major study in 1946.* In November, 1947, 6 national nursing organizations† formed the present Committee on the Structure of National Nursing Organizations to recommend new structure.

This committee, comprising 60 leading nurses from all over the country chosen by the 6 organizations, in the spring produced a "Tentative Plan for One National Nursing Organization"‡ which was widely circulated among nurses with a request for study and further development.

The plan recognized that nursing

* See "Report on the Structure of Organized Nursing," by Raymond Rich Associates, *American Journal of Nursing*, October, 1946.

† American Association of Industrial Nurses, American Nurses' Association, Association of Collegiate Schools of Nursing, National Association of Colored Graduate Nurses, National League of Nursing Education, and National Organization for Public Health Nursing.

‡ Printed in May, 1948, *American Journal of Nursing* and available in reprint form from Committee on Structure, Room 201, 1790 Broadway, New York 19, N. Y.

faces a dual task: (1) providing better nursing service to the people of the United States, and (2) promoting and protecting the interests of the members of the nursing profession.

While there is no clear line of demarcation between the two tasks, obviously non-nurses, the "consumers" of nursing service, have a vital interest in and responsibility for seeing that adequate nursing services are available. Many purely professional questions, on the other hand, would need to be settled by nurses alone. This dual nature of organized nursing activity is one reason why separate organizations have grown up. Thus the American Nurses' Association is made up of nurses only, while the National Organization for Public Health Nursing, with its focus on community service, and the National League of Nursing Education, which concentrates on education, admit to membership both nurses and non-nurses.

The "Tentative Plan" attempted to reconcile the two approaches by setting up divisions within the one organization to deal with service and education questions. The plan proposes that individual non-nurses, schools of nursing, and nursing services be offered full participation in division activities.

First major commentary on the plan came during the Biennial Convention of the ANA, NLNE, and NOPHN in Chicago in early June.

The ANA House of Delegates, voting on questions placed before it by its board of directors, approved:

1. One national nursing organization
2. Local, state, and national units for the new organization
3. Inclusion of non-nurse members in a single organization

A fourth question as to whether or not non-nurse members should have the right to vote and hold office was referred back to the Committee on Structure for further study.

The NOPHN decided to refer the question of approval of one organization to a vote of its entire membership. Members at the convention approved principles stating that:

"1. A satisfactory organization for the advancement of nursing should include nurse and non-nurse participation with equal rights as members, except in specified areas which should be under the control of professional nurses.

"2. Provision should be made for the membership of agencies engaged in nursing service and nursing education.

"3. Public health nursing, as one of the specialties, should have sufficient autonomy to define standards for service and qualifications for practitioners for its own field, as well as the responsibility for interpreting and effectuating its program."

The NLNE voted that, "Citizens, including members of related professional organizations, should have voice and vote in planning for nursing service and nursing education."

CANADA'S NEW DEAL IN HEALTH

At the recent meeting of the Canadian Public Health Association in Vancouver, B. C., the Honorable Paul Martin, Canadian Minister of National Health and Welfare, declared that "a new era has opened for public health in Canada." He referred to the statement of the Canadian Prime Minister to the Parliament on May 14 as "a memorable occasion in the history of public health in Canada. . . . Remote objectives have now become proximate and possible."

On that day the Prime Minister announced a three-point program to marshal financial resources of the nation in support of the health services of the Canadian Provinces.

The three items for which federal grants are now provided are: (a) grants for health surveys totalling \$625,000, (b) grants for health services of \$17,000,000 in the first year and rising

eventually to \$22,000,000, and (c) grants for hospital construction of \$13,000,000 a year for 5 years, with probably \$6,500,000 annually for the 5 years thereafter.

Beginning in 1949 the Canadian federal government will make available more than \$30,000,000 for health services, more than four times what it is currently spending, and about half of what the provinces are now spending and almost twice municipal health expenditures.

The survey grants are made to the provinces so that they may study their existing needs and plan the machinery for extending hospital care and organizing hospital and medical care insurance.

The health grants are in eight areas; for general public health services 35 cents per capita, rising the fourth year to 50 cents per capita, and totalling \$6,500,000; tuberculosis control, \$3,000,000 to \$4,000,000; mental health care, \$4,000,000 to \$7,000,000; venereal disease control, crippled children's services, and professional training, each \$500,000; public health research, \$100,000 to \$500,000; cancer control, \$3,500,000. The grants for hospital construction are expected to provide more than 40,000 hospital beds.

The Minister of Health indicated clearly the direction the Dominion Government is taking when he said, "When the present program is well under way, it will then be possible to proceed with the implementation of a national plan for hospital and medical care insurance. . . . It prepares the way for Health Insurance by putting into effect those steps that are the essential prerequisites to any adequate national plan."

The new program takes full account of primary provincial responsibility for health under the Canadian Constitution. Mutually acceptable conditions govern-

ing grants will be worked out coöperatively between federal and provincial governments; administration will be entirely under provincial jurisdiction. Said the Minister of health, "The provinces have built modern and efficient health services for their peoples—the National Health grants will permit them to extend their programs and to do the sort of job all who work in the public health field have long wanted to get ahead with."

The Prime Minister's statement of May 14 carried forward further the national health program included in the Dominion Proposals to the Provinces in August, 1945, after study of the Canadian health scene. At that time a National Health Insurance Scheme was already a definite goal. Since 1945 a special Division of Health Insurance studies has been working on foundation plans for the formulation of health insurance legislation.

FIRST INTER-AMERICAN SANITARY ENGINEERING CONGRESS

The first Congress of the Inter-American Association of Sanitary Engineering was held early in April in Santiago, Chile. More than 250 members of the Association from nineteen of the American Republics were present, with particularly large delegations from Argentina, Brazil, Peru, and Venezuela. The Congress was opened by the President of Chile, Mr. Gabriel Gonzalez Videla. The officers elected for the ensuing year were: President, Clarence I. Sterling, Jr., Director of Health and Sanitation Division of the Institute of Inter-American Affairs; Vice-President, Alberto Ortiz Irigoyen, Chief, in Charge of Construction, Secretaria de Recursos Hidraulicos, Mexico; Secretary, Donald L. Snow, Sanitary Engineer, Pan American Sanitary Bureau.

The next Congress of the Association will be held in Mexico City in 1949.

FIRST RESEARCH CLINIC TO STUDY MULTIPLE SCLEROSIS

In March the first of a projected series of research clinics in multiple sclerosis was opened in Boston and operated jointly by the Beth Israel and the Boston State Hospitals. This was made possible through a grant from the National Multiple Sclerosis Society which hopes to open another such clinic at the Albany Hospital, Albany, N. Y., in the near future. Others will be opened in leading cities as funds permit.

The Boston clinic and others to be opened will be devoted to research into the causes of multiple sclerosis and the means of control. Red Cross coöperation in Boston is providing ambulance service to bring home-bound patients to the clinic.

Another recent activity of the National Multiple Sclerosis Society was the distribution to about 76,000 physicians in the United States of a manual of information on the diagnosis and treatment of multiple sclerosis prepared by the Society's Medical Advisory Board. With this was a letter asking the number of multiple sclerosis patients being treated by the physician. An extensive survey of the incidence of the disease by the Society's Statistical Committee, is now being planned with the coöperation of the U. S. Public Health Service, under the chairmanship of Lawrence C. Kolb, M.D., of the Service.

HEALTH ADVISORY COMMITTEE TO UAW-CIO

The health and welfare activities of the United Automobile Workers-CIO have been coöordinated in a Social Security Department which is under the direction of Harry Becker, formerly of the U. S. Children's Bureau.

In order to have medical guidance in developing the program that is contemplated in the Union's negotiations for a health and welfare fund, a health and medical care advisory committee

has been appointed by the Social Security Department. The members of this committee are: George Baehr, M.D., President of the New York Academy of Medicine; Dean Clark, M.D., Medical Director of the Health Insurance Plan of Greater New York; Basil C. MacLean, M.D., Director of the Strong Memorial Hospital, University of Rochester, Rochester, New York; John Peters, M.D., Professor of Medicine, Yale University College of Medicine; Ernest Stebbins, M.D., Director of the School of Hygiene and Public Health, Johns Hopkins University; F. D. Mott, M.D., Chairman of Health Services Planning Commission, Department of Public Health, Saskatchewan, Canada; Dr. Frank Weiser, Director of Education and Research at Grace Hospital, Detroit, Mich.; Katherine Faville, M.Sc., Dean, College of Nursing, Wayne University; and Ethel Cohen, Director of Medical Social Services, Beth Israel Hospital, Boston.

DALLAS MUSEUM INITIATES ANNUAL AWARD

Robert L. Sutherland, M.D., Director of Mental Hygiene of the Hogg Foundation of the University of Texas, received the first annual award of the Dallas Health Museum on April 28 in connection with the first public meeting of the Texas State Medical Association in Houston. The award, in the form of a plaque, was made for Dr. Sutherland's contribution to mental health in Texas, particularly in stimulating acceptance of local responsibility in mental health education. The presentation was made by Haven Emerson, M.D.

ANNIVERSARY OF THE DISCOVERY OF RADIUM

At an American Cancer Society dinner in Philadelphia March 31, commemorating the 50th anniversary of the discovery of radium by Pierre and Marie Curie, their daughter Mlle. Eve

Curie, French author and journalist, received a \$10,000 grant for the work of Dr. Antoine Lacassagne of the Radium Institute in Paris. Mlle. Curie said that the money would be used to buy an infra-red spectograph for the Institute.

RURAL MEDICAL STUDENT LOAN FUND

A revolving loan fund to be known as the "Fund for the Encouragement of Medical Practice in Rural Areas" has been created by the Michigan Foundation for Medical and Health Education. A hundred man State Campaign Committee was recently formed with a goal of "\$50,000 in Five Months," for the rural practice project. Announcement was made at a Foundation breakfast March 11 at Detroit.

RESEARCH FELLOWSHIPS—THE AMERICAN COLLEGE OF PHYSICIANS

The American College of Physicians announces that a limited number of Fellowships in Medicine, with a stipend from \$2,200 to \$3,200, will be available from July 1, 1949, to June 30, 1950. These are designed to provide opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation. They are for the benefit of physicians in the early stages of preparation for a teaching and investigative career in internal medicine. Assurance must be provided that the applicant will be acceptable in the laboratory or clinic of his choice and that he will be provided with the facilities necessary for the proper pursuit of his work.

Application forms, available from The American College of Physicians, 4200 Pine Street, Philadelphia 4, Pa., must be submitted in duplicate not later than November 1, 1948.

WHO MAKES A MOVIE

"The Eternal Fight" is the title of WHO's first documentary film which is being produced by Madeleine Carroll

Films, Inc., for the UN Film Board. It will show the work of WHO, particularly in epidemic control. The film will be shot at Lake Success, Geneva, Paris, and Egypt, and dramatizes the growth of international coöperation in epidemic control. The danger of epidemics has been increased due to ever-increasing speed of transportation, while the means of controlling them have been developed by medical and public health men all over the world.

To be completed late in the summer of 1948, the film, about 20 minutes in length, will be available in 35 mm. and 16 mm. It will be distributed by the United Nations through theatrical and non-theatrical distributors in member countries.

MENTAL HYGIENE FELLOWSHIPS

The U. S. Public Health Service has announced a limited number of mental hygiene research fellowships. These are open to psychiatrists, psychologists, social workers, anthropologists, sociologists, and others with proper qualifications. A pre-doctorate research fellowship carrying a stipend of \$1,200 a year is available to those with a bachelor's degree, of \$1,600 for those with a master's degree or its equivalent in graduate work. For those with dependents the stipends are \$1,600 and \$2,000 respectively. Tuition will also be paid. Medical students who have completed one or two years of medical work may also apply.

A post-doctorate research fellowship, to be awarded to qualified individuals holding a doctor's degree in medical or related fields, carries a stipend of \$3,000 (\$3,600 for doctors with dependents), but not including tuition. Also offered is a special research fellowship to those who qualify for a post-doctorate fellowship and in addition have demonstrated outstanding ability or possess specialized training. This fellowship does not carry a set stipend,

the amount being determined in the individual case. Additional information may be obtained from Division of Research Grants and Fellowships, National Institute of Health, Bethesda 14, Md.

COURSES FOR SUPERVISORS OF STUDENT HEALTH

New York University in its School of Education's Department of Physical Education and Health has completed the first year of a new curriculum designated as "Courses for Supervisors of Student Health." The course, leading to a bachelor's or master's degree, is designed to prepare graduate registered nurses and other qualified students for positions as supervisors of student health in colleges and schools of nursing. Its first class included seven students.

The courses and promotional work were planned by a committee of ten, representing the university faculty, official and voluntary health agencies, schools of public health, and colleges.

The program has been made possible through a grant of funds from the Helene Fuld Health Foundation. It is in charge of Ella F. Harris, M.D., assistant professor in the Department of Physical Education and Health. She should be addressed at New York University, Washington Square, New York, for information as to the program for 1947-1948.

CUTTER DEXTROSE SOLUTIONS BACK IN DISTRIBUTION

The June *Journal* (p. 819) printed the Cutter Laboratories' telegram recalling all its dextrose solutions. On June 21 the following statement was released, indicating that these solutions are again being distributed safely:

"We are now ready to resume shipment of Cutter solutions in Saftiflasks from our Berkeley and branch warehouses.

"We wish we could tell you that the cause of the contamination is now defi-

nitely known. We cannot truthfully do so. In the six weeks since we recalled our solutions, hundreds of thousands of flasks have been critically examined. Every piece of equipment and every instrument was meticulously checked. There was no evidence of equipment or instrument failure, and we could not definitely confirm closure failure or any other cause.

"We can assure you, however, that not a single bottle which was clear on visual inspection has been found to be contaminated, and that we will continue to do everything in our power to assure the safety that has been the cornerstone of our existence and growth for over fifty years."

MIDDLE STATES HEALTH EDUCATORS MEET

On May 14 and 15, the second annual conference of the Middle States Region Health Educators was held at Des Moines, Iowa, with 94 persons representing Indiana, Illinois, Iowa, Kansas, Michigan, Minnesota, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin in attendance. There were fruitful discussions on training, school health, health councils, and the responsibilities of health educators. Discussion indicated that health education is penetrating two new fields—industry and hospitals.

A third conference is planned for the spring of 1949.

ENVIRONMENTAL SANITATION REFRESHER COURSE

A one week in-service training course, designed specifically as a practical refresher course for qualified public health personnel, interested in environmental sanitation will be held September 13-17, 1948, at the University of Massachusetts. This training program is intended for but not limited to residents of Massachusetts.

The program is sponsored by the uni-

versity Department of Bacteriology and Public Health, in coöperation with other university departments and federal and state agencies. There will be one day sessions on each of the following subjects: Milk Sanitation, Industrial Sanitation, Restaurant Sanitation, Water and Sewage Sanitation, Rodent and Insect Control.

For application forms, apply to the Director of Short Courses; for details, to the Department of Bacteriology and Public Health, University of Massachusetts, Amherst.

WEST VIRGINIA PUBLIC HEALTH ASSOCIATION

The West Virginia Public Health Association held its 1948 Annual Meeting in Huntington on May 27 and 28. Over three hundred persons attended this meeting, making it the largest gathering of West Virginia public health workers.

An Industrial Hygiene Section and a Clerks' Section were established and meetings were arranged for these and other groups within the Association.

The American Public Health Association was represented at the meeting by Roscoe P. Kandle, M.D., Field Director. New Officers for 1948-1949 are as follows:

President—L. A. Dickerson, M.D., Charleston.

1st Vice-President—Charlotte McLoughlin, Charleston.

2nd Vice-President—H. B. Wise, M.D., Weston.

Exec. Secy.—Annette King, Charleston.

DR. CHESLEY HONORED BY MINNESOTA STATE MEDICAL ASSOCIATION

On June 8 at the meeting of the Minnesota Medical Association, the House of Delegates unanimously voted that the Distinguished Service Medal of the Association be awarded to Dr. Albert Justus Chesley "in recognition of his nearly half a century of outstanding service in the field of public health and social hygiene, not only in Minnesota

but elsewhere in the United States and abroad; and for his rare insight and fine understanding of the private practice of medicine to which, as one of its most ardent advocates, he has given unflinching coöperation at all times."

UTAH PUBLIC HEALTH ASSOCIATION

The Utah Public Health Association held its Annual Meeting in Salt Lake City May 25 to 27 and elected the following new officers at that time:

President—L. P. Gebhardt, M.D., Salt Lake City.

President-Elect—J. P. Kesler, M.D., Ogden.

Vice-President—W. F. Bulkley, D.D., Salt Lake City.

Secretary—Dean A. Anderson, Ph.D., Provo.

Treasurer—Lena Besendorfer, Salt Lake City.

NEW ENGLAND HEALTH INSTITUTE MEETS IN AMHERST

A session of the New England Health Institute, in combination with the annual meeting of the Massachusetts Public Health Conference, was held at the University of Massachusetts, Amherst, under the sponsorship of the Massachusetts Public Health Association, the University of Massachusetts, and the Massachusetts Department of Public Health, June 16-18. About 600 persons were registered, including representatives of New England states, both official and voluntary, for the three day session.

The opening address was presented by Ira V. Hiscock, Sc.D., Professor of Public Health at the Yale School of Medicine, New Haven, on "The Scope of a Health Program." Other features included panels on "Improvement of Local Health Services," "Chronic Illness—A Challenge to Public Health," "Citizens' Committees: How to Develop and Keep Them Active," laboratory and environmental problems, a panel on "Community Nutrition Services in Action," and another on "Health Needs of the Child."

Featured speakers included Warren F. Draper, M.D., American Red Cross, Washington; Martha M. Eliot, M.D., President, American Public Health Association; Vlado A. Getting, M.D., Commissioner, Massachusetts Department of Public Health; Franz Goldman, M.D., Harvard School of Public Health; Hugh R. Leavell, M.D., Harvard School of Public Health; Leonard A. Scheele, M.D., Surgeon General, U. S. Public Health Service, Washington; V. A. Van Volkenburgh, M.D., New York State Department of Health, Albany; Charles F. Wilinsky, M.D., Beth Israel Hospital, Boston, President, Massachusetts Public Health Association and President-Elect, American Public Health Association.

HEALTH NEWS FROM HAWAII

The Public Health Committee of the Chamber of Commerce of Honolulu has recently announced an appropriation of \$18,000 to be used in the establishment of a diagnostic and treatment clinic for cancer.

According to Ray G. Nebelung, Dr. P.H., Executive Director, the committee has also established two scholarships in the amount of \$2,500 to be made annually to local individuals already in public health or planning to enter the field. The first recipients include one student of health education at the Yale School of Medicine, New Haven, and another who will spend 15 months in Boston and New York in sight conservation.

In September, the Public Health Committee is sponsoring a sanitation week at which time Professor Walter Mangold from the University of California School of Public Health will conduct an intensive in-service training program for the Board of Health personnel. In connection with this activity business and civic leaders are planning in coöperation with health department officials to undertake an activity pro-

gram to emphasize the importance of sanitary environment and to offer the citizens an opportunity to learn what services are provided and what part they may play in improving conditions from a sanitary standpoint.

The Oahu Health Council has been active in preparing a program of proposed health legislation to be sponsored in the next session of the legislature.

During the last three years studies have been under way on eight areas of post-war interest in public health. The report is shortly to be released.

U. S. CONGRESS ENACTS LEGISLATION ON HEART DISEASE

In early June the U. S. Congress completed consideration and approved a national program to curb cardiovascular diseases by stimulating research, professional training, and public control measures. The initial appropriation is about three million dollars and, according to the *Washington Report on the Medical Sciences*, more than half is earmarked for research grants in aid to universities, hospitals, laboratories, and other institutions, as well as to individuals whose projects may be approved. Briefly, the new law establishes a national heart institute which will be housed in the forty million dollar clinical research center to be erected in Bethesda, Md., create a national advisory heart council composed of federal medical service representatives and twelve prominent citizens divided equally between scientific authorities and laymen, provide for fellowships, and directs the Surgeon General to assist state and local governments in setting up diagnostic and control programs. This legislation has had the consistent support of the American Heart Association, a member of the National Health Council, but the National Heart Committee formed recently with headquarters in New York has issued a statement claiming for

itself credit for being the spearhead of the drive.

During the same week the American Foundation for High Blood Pressure with headquarters in Cleveland announced that it had allocated \$75,000 for research in hypertension, arteriosclerosis and associated conditions.

DR. BERGSMA APPOINTED NEW JERSEY COMMISSIONER OF HEALTH

Daniel Bergsma, M.D., M.P.H., took office as State Commissioner of Health in New Jersey on June 1, having been nominated by Governor Driscoll and approved by the State Senate. Dr. Bergsma's appointment is the first as State Commissioner of Health under the revised statutes of New Jersey which reorganized the State Department of Health under the new Constitution.

Joining the New Jersey State Department of Health in 1938 as a medical assistant, Dr. Bergsma served as Chief of the Bureau of Venereal Disease Control from 1940 until 1942 when he entered the Army Medical Corps. A native of New Jersey, Dr. Bergsma was born in 1909, and is a graduate of Oberlin College and Yale University School of Medicine. In 1946 he received the M.P.H. degree from the University of Michigan.

Dr. Bergsma advanced through the Medical Corps from the entering rank of Captain and was promoted to Colonel in 1946. During the war he was assigned to the Headquarters of the Eastern Defense Command and First Army and later at Headquarters in the Caribbean Defense Command in the area covering troops in Central America and the countries of northern and western South America, with assignment as Assistant Theater Surgeon. He is a recipient of the Legion of Merit, Headquarters Caribbean Defense Command. Dr. Bergsma is a Fellow of the A.P.H.A., and is Vice-President of the

New Jersey Health and Sanitary Association.

ARMY SYPHILIS RECORDS

The Veterans Administration has in its custody the majority of syphilis records of those Army personnel who were treated for this disease while in active service, and in many instances can procure informative data from the syphilis records of other than Army personnel. It is thought that many physicians treating veterans for syphilis as private patients would find a résumé of the syphilis record useful since the details of treatment, results of spinal fluid examinations, and blood serologies are incorporated in the records.

Résumés of these records are available to physicians who are treating such veterans provided authorization for the release of the data is given by the veteran. Requests for the résumés accompanied by an authorization for the release of the data, dated and signed by the veteran, should be addressed to the Dermatology and Syphilology Section, Veterans Administration, Munitions Building, Washington 25, D. C. It is most important that the veteran's Service Serial Number and other identifying information, such as the date of enlistment, the date of discharge, rank, and organization be included.

Ordinarily, the résumés can be furnished in approximately two weeks from the date of the receipt of the request and signed authorization.

ILLUMINATING ENGINEERING SOCIETY

ELECTS L. E. TAYLER PRESIDENT

Lee E. Tayler of the Detroit Edison Co., Detroit, Mich., has been elected President of the Illuminating Engineering Society to take office October 1, 1948.

Other officers elected are: General Secretary, A. H. Manwaring, Philadelphia Electrical & Mfg. Co., Philadelphia; Treasurer, E. M. Strong, Cornell

University, Ithaca, N. Y.; Vice-President, Walter Sturrock, General Electric Co., Cleveland, Ohio; Directors, Myrtle Fahsbender, Westinghouse Electric Corp., Bloomfield, N. J.; Hoyt Steele, Benjamin Electric Mfg. Co., Des Plaines, Ill.

DRS. TAUSSIG AND BLALOCK RECEIVE PASSANO AWARD

The 1948 Passano Foundation award was presented to the Taussig-Blalock team which developed the operation popularly known as the "blue baby operation." Presentation of the \$5,000 cash award was made June 23 at the Palmer House, Chicago, during the Annual Session of the American Medical Association. Since this operation was first undertaken in November, 1944, more than 600 patients drawn from all parts of the world have been operated on at Johns Hopkins Hospital alone. Dr. Helen B. Taussig is Associate Professor of Pediatrics and Dr. Alfred Blalock is Professor of Surgery at Johns Hopkins University School of Medicine.

The Williams & Wilkins Company of Baltimore established the Passano Foundation in 1944 to aid in the advancement of medical research, especially research which promises clinical application.

CANADIAN PUBLIC HEALTH ASSOCIATION

The following are the new officers of the Canadian Public Health Association as elected at the 36th Annual Meeting in Vancouver, May 17-20, 1948:

Honorary President:

The Hon. F. R. Davis, M.D., Halifax N. S.

President:

Allan R. Morton, M.D., Halifax, N. S.

President-Elect:

John T. Phair, M.D., Toronto, Ont.

Vice-Presidents:

Elizabeth Russell, R.N., Winnipeg, Man.

George D. W. Cameron, M.D., Ottawa, Ont.

S. Stewart Murray, M.D., Vancouver, B. C.

Honorary Treasurer:

William Mosley, M.D., Toronto, Ont.

Editor, Canadian Journal of Public Health:

Robert D. Defries, M.D., Toronto, Ont.

Executive Director:

J. H. Baillic, M.D., Toronto, Ont.

WHO TRAINS TUBERCULOSIS FELLOWS IN DENVER

Four fellows, appointed by the Interim Commission of the World Health Organization from various countries, on July 1 began 6 months' free instruction in methods of tuberculosis prevention, control, and treatment at the National Jewish Hospital, Denver, Colo. Beginning January 1, 1949, the World Health Organization will send annually twelve who will receive instruction at this hospital, the University of Colorado School of Medicine, Fitzsimons General Hospital, and other Denver institutions. Traveling expenses will be financed by the organization. Living expenses will be contributed by the International Foundation for Medical Research and Education.

ROUTINE CHEST X-RAY OF HOSPITAL ADMISSIONS

Beginning early in May, Morrisania Hospital, one of New York's municipal hospitals, began routine chest x-ray examinations of all incoming patients. The x-ray machine and technicians for the project are being furnished by the Bronx Committee of the New York Tuberculosis and Health Association. It is expected that the demonstration will be so effective that it will be installed in other municipal hospitals of the city.

NEW HOME FOR CHICAGO TUBERCULOSIS INSTITUTE

The Tuberculosis Institute of Chicago and Cook County has acquired its own building in an effort to keep pace with a rapidly expanding program. Since its founding in 1906, the Institute had rented space at 5 different locations, moving into larger quarters as public support of the program increased. The building, ideally suited to the Institute's tuberculosis eradication program, is sit-

uated in the area with the greatest tuberculosis incidence in the city. Last year 532 cases were reported in the area.

The officers, staff, and directors of the Institute entertained approximately 500 persons at "Open House" at the new address, 1412 W. Washington Blvd., on April 16. A mobile unit was stationed at the front door and free chest x-rays were made of all visitors. Other features included exhibits on tuberculosis, pictorial displays of staff activities, and continuous showing of films and slides.

STONE-MARSHALL TEST PAPER CHANGES HANDS

Charles G. Marshall, President of the Chemiatric Corporation, Sparta, N. J., announces the acquisition from the Universal Chlorinator Company of all patent rights to the Stone-Marshall test paper, utilized for testing quaternary ammonium compounds used in the food, dairy, and allied industries. Samples of the test paper are available.

MR. BURRITT RETIRES FROM NATIONAL HEALTH COUNCIL

Bailey B. Burritt resigned as Executive Director of the National Health Council on June 30, 1948. Early in 1947, Mr. Burritt was induced to come out of retirement to devote himself to the National Health Council's new nation-wide health program until such time as a permanent director was secured. He had retired in 1944, as Senior Executive Director of the Community Service Society of New York after 30 years during which he was instrumental in bringing health services within the reach of thousands of New York families.

During the year and a half since Mr. Burritt became its Executive Director, the National Health Council has assumed renewed leadership among its

national public health agency members and has stimulated interest and action throughout the country in behalf of effective, forceful public health programs.

Commenting on Mr. Burritt's resignation Philip R. Mather, President of the Council said, "Mr. Burritt came to the National Health Council with years of fruitful service in behalf of the public already behind him. His seasoned judgment, wise counsel, and strong leadership have been invaluable in laying the foundation for the long range program of the Council. It was with greatest reluctance and in deference to Mr. Burritt's urgent request that the Board of Directors accepted his resignation at this time."

The work of the Council will continue under the administration of John W. Ferree, M.D., Associate Director since May, 1947, until a successor to Mr. Burritt is appointed. Working in close coöperation with Mr. Burritt, he has been engaged principally in helping local and state health councils to broaden the scope of their usefulness and in stimulating the organization of new councils to increase the effectiveness of the local health programs.

Dr. Ferree entered public health work in 1936 as Chief of the Bureau of Local Health Administration of the Indiana State Board of Health, and from 1940 to 1942 was State Health Commissioner of Indiana. He later served in the U. S. Navy, Division of Preventive Medicine, until 1945, reaching the rank of Commander. Before joining the National Health Council he was Director of the Division of Education of the American Social Hygiene Association, a member agency of the National Health Council.

BUILDING FROZEN FOOD LOCKER PLANTS

Recognizing the growing importance of frozen food locker plants, the Com-

mittee on Sanitary Engineering and Environment, Division of Medical Sciences of the National Research Council (Washington, D. C.) recently published a report entitled, "Control of Frozen Food Locker Plants." Possible health problems that may be found in these plants through design or operation are discussed. Recommendations for the construction and operation of frozen food plants are given as follows:

1. Operators who propose to build locker plants should have plans drawn up under the supervision of a competent engineer and secure the approval of the state health authority for these plans before construction is begun.

2. To prevent heat infiltration and thus encourage the maintenance of low temperatures, special attention should be given to the construction of floors, walls, and ceilings of cold rooms and to the conductance of building materials.

3. Separate compressors of the same make should be provided for the chill, sharp-freeze, and storage rooms. Each compressor should have sufficient capacity to carry the whole cooling load and should be installed so that it can readily be used for any one of the services.

4. Standby electric service should be provided wherever possible.

5. Locker plant operators should consider future developments such as operating slaughter houses, meat and food processing plants, kitchens, and bakeries.

6. Locker plant regulations should safeguard the public health, provide for sanitary operation of plants, but avoid unnecessary details that might obstruct individual initiative and progress.

The subcommittee preparing this report consisted of W. D. Tiedeman, V. M. Ehlers, and L. F. Warrick. The Chairman of the Committee on Sanitary Engineering and Environment is Dr. Abel Wolman.

PERSONALS

Central States

CHARLES H. MILLER, JR., M.D., has recently been appointed Health Officer for the newly established four-County Health Department, which includes Hardin, Johnson, Massac, and Pope counties, Illinois. Dr. Miller has served as District Health Superintendent and also in the State Department of Public Health.

Eastern States

MARTA FRAENKEL, M.D.,* formerly Research Associate with the Department of Preventive Medicine, Long Island College of Medicine, Brooklyn, N. Y., has become Research Director of the New York State Joint Legislative Committee for the Study of Cerebral Palsy in the Albany headquarters of the New York State Health Department.

MARIAN MCBEE, Executive Secretary of the New York Committee on Mental Hygiene, has been elected President of the American Orthopsychiatric Association for 1949-1950.

ANTONIO P. MILONE, M.D.† has been appointed Health Officer of North Adams, Mass., effective September. In addition to his private practice, Dr. Milone has served since 1946 as part-time school medical inspector in the Boston Health Department.

JAMES O. WAILS, M.D.,* retired as Health Commissioner of Worcester, Mass., on June 30. Before assuming his duties in Worcester in 1943, he was Director of the Nashoba Health District with headquarters at Ayer.

Southern States

C. H. BENNING, M.D.,* was named City Health Officer of Tulsa, Okla., effective May 1.

ABRAHAM GELPERIN, M.D., M.P.H.† was appointed Director of the Bureau of Communicable Diseases (includ-

ing venereal disease control) in the New Haven, Conn., Department of Health, as of May 17. Since 1946 he has been a member of the staff of the Johns Hopkins School of Hygiene and Public Health in Baltimore, Md.

EDGAR ERSKINE HUME, M.D., Dr.P.H.,* has been promoted to the permanent rank of Brigadier General in the U. S. Army Medical Corps. General Hume, during World War II, participated in the African, Sicilian, and Italian campaigns. He was Chief of Public Health in Sicily in 1943.

EDWARD F. KNIPLING, M.D., as Director of the Orlando Station of the Bureau of Entomology and Plant Quarantine of the U. S. Department of Agriculture during the war period, was awarded the Medal of Merit on May 20 by the Department of National Defense. The citation, signed by President Harry S. Truman, reads in part, "Dr. Knipling planned and directed investigations for the development of insecticides and repellents for the prevention of insect-borne diseases in the United States Army." Dr. Knipling is at present in charge of the Division of Insects Affecting Man and Animals, of the U. S. Department of Agriculture, Washington, D. C. He was notified early this year that he was also to be awarded Great Britain's highest decoration to civilians, The King's Medal for Service, for his part in the same investigations.

ABRAHAM J. KRELL,† has accepted a position with the Layne-Texas Company, Ltd., Dallas, Tex., in charge of the newly organized Water Treatment Division. He was formerly Sanitary Engineer, Technical Service and Sales Division of the General Filter Company, Dallas.

J. W. MARKLEY, M.D., was appointed

July 1 as Director of the recently created Bureau of Hospital and Medical Care, West Virginia State Department of Health.

R. G. MEADER, Ph.D., has been appointed Deputy Chief, Cancer Research Grants Branch of the National Cancer Institute, Bethesda, Md., effective June 1. Dr. Meader will be responsible for securing scientific review of applications for federal cancer grants, for maintaining contact with investigators in fields bearing on cancer research, for analyzing the grant-in-aid program of the National Cancer Institute in relation to programs of other agencies supporting cancer research, and liaison with those agencies.

I. O. POLLOCK, M.D., on May 1, became Director of the five-county Health Department which serves Adair, Cherokee, Delaware, Mayes, and Sequoyah counties in Oklahoma, with headquarters in Tahlequah.

Western States
